INTRODUCTION

The plastics industry is one of the fastest growing major industries in the world. Every year there is an increase in the amount of plastics used in all types of products. A good example of this is the percent of plastics used in today's automobiles compared to 15 years ago.

The continued rate of growth in the industry hinges on the development of improved and new thermoplastics with greater physical properties. This has opened the door to applications never thought possible before. These are emerging both as product innovations and as existing products converted from materials such as metal, glass, wood or paper to plastics for competitive and economic advantage.

The plastics injection molding field, at large, is volume oriented. Vendor sources, particularly mold makers and custom molders, are geared to long tool life and high volume production. Plastics equipment manufacturers, likewise, have concentrated almost exclusively on fully automatic, sophisticated injection molding machines whose economics lie in single runs of 100,000 parts or more and in multi-shift operations.

The Morgan Industries equipment line has been specifically designed to serve short-run plastics requirements at the most economical level and with a maximum of operating flexibility. But equipment is only part of the picture; the other part is tooling.

The purpose of this document is to illustrate, based on many years of accumulated experience in short-run plastics, simple and straight forward approaches to the design and building of tools and dies for use in a Morgan-Press. The emphasis is heavily on cutting costs and tooling lead times through the use of your own and/or your company's design and machining skills. The approach is one of reducing the tool to its fundamentals by segmenting it into basic parts.

Definition of Short-Run Plastics

In order to prevent any misconception, we are defining short-run as production in which annual requirements for a particular part range between one and 25,000 parts. Typical of these are non-standard or engineered plastic parts whose piece cost is presently above $.25. Recognizing the wide substitution possible between metals and plastics, it is not necessary to limit applications to parts which are presently in plastic. As your experience grows, you will want to analyze the merits of converting a number of non-plastic parts or components to this material.

The Morgan-Press will accommodate up to a four-ounce part (in styrene) which equals about 6 cubic inches in volume; its most efficient production is in its mid-size shot range where material melting time is not a primary constraint.

Thus, if your company has a product line whose annual unit production is under 25,000 and in which some parts are costly due to high labor content, or require long lead times, we highly recommend that these parts be evaluated for plastics tooling and molding on a Morgan-Press.

Economics of Short-Run

Chapter V sets forth a wide number of examples of simple tools designed for various plastic parts. Cost savings are in an impressive range of 44 to 94 percent of other traditional approaches and the reduction of lead times is equally significant.

These examples have been analyzed on a total cost basis amortizing the tool over the production of a single year. At the same time, we should point out that the tool life is assumed to meet three to five years of production.

The cost savings over alternate production methods are realized through the following features:

- Tools designed and built as Class B or C tooling (see Chapter II, page 10): all areas which do not require finish or tolerances are completed in the rough; heavy cost cutting is concentrated on the tool base, ejector systems, use of inserts and the reduction or elimination of heating and cooling systems.

- These tools are meant to operate according to predetermined quantity requirements. For example, if 50-100 large parts per set-up are intended, the tool plates might be bolted together rather than be built to withstand high clamp pressures.

- Likewise, the tools are designed to last the life of a short-run tool rather than several million parts. The life factor is geared to anticipate 2-5 year production requirements <u>as well as</u> to anticipate part or product obsolescence.

- Very often, as an added means of maintaining the total economics of a year's production run, a tool will be designed to complete about 80 percent of the part detail. Limited machining of the parts on simple jigs is then required to complete them. This approach is also used to achieve extremely tight or critical tolerances.

On balance, the economics of the proposed short-run tools lie in flexible design to meet intended production requirements in terms of quantity, quality, product obsolescence and labor input.

In addition, the economics of managing a Morgan-Press set-up take on major significance:

- Parts need no longer be purchased and inventoried according to vendor quantity discount. A Morgan-Press tool can be set up in minutes, used to run a month's inventory and then stored once again. Inventory then consists primarily of tools.

- Acquisition of parts will no longer require the overheads of purchasing requisition, order, invoice and disbursement controls.

- All lead times including first-run and subsequent productions are now fully controlled by production management.

- All quality assurance is fully controlled by and responsive to production management.

- Morgan-Presses require only compressed air and 120 volt electrical for operation thus avoiding the high operating costs of production equipment.

- Morgan-Presses have a small factory "footprint" and do not require a lot of space to be set-up and operated.

- Morgan-Presses, due to easy portability, can be moved from one location to another when and where required.

If you have a short-run production problem involving high costs, heavy inventory, unacceptable lead times or quality control, and if your company has engineering and machining capabilities, we invite you to consider this unique opportunity.

* * *

We strongly feel that the development of the proposed approach to production - particularly by beginning with a few of the more simple short-run parts required in your production and the development of some good case examples of your own - will provide the solution to many of your problems in short-run and will cause you to convert many parts to this method.

Many of our Morgan-Press users state that their unit paid for itself within the first year. We invite you to do the same, generating significant profits and making a real name for yourself in your company.

CHAPTER ONE

INJECTION MOLDING PROCESS

THEORY OF INJECTION MOLDING

The theory of injection molding can be reduced to four simple individual steps: Plasticizing, Injection, Chilling, and Ejection. Each of those steps is distinct from the others and correct control of each is essential to the success of the total process.

Plasticizing describes the conversion of the polymer material from its normal hard granular form at room temperature, to the liquid consistency necessary for injection at its correct melt temperature.

Injection is the stage during which this melt is introduced into a mold to completely fill a cavity or cavities.

Chilling is the action of removing heat from the melt to convert it from a liquid consistency back to its original rigid state. As the material cools, it also shrinks.

Ejection is the removal of the cooled, molded part from the mold cavity and from any cores or inserts.

Repetition of these basic steps in sequence is the process of injection molding.

THE PRACTICE OF INJECTION MOLDING

The practice of injection molding varies from the theory, only in as much as process limitations and available equipment affect it.

Step by step the process as practiced is as follows:

Material Preparation

Before the thermoplastic material is plasticized, it may be necessary to do some simple yet essential preparation.

Drying

Many materials are hygroscopic and will absorb moisture from the atmosphere. This moisture may be absorbed into the granules, it may adhere to the outer surface of the material, or both. It is absolutely essential that this moisture be driven off before plasticizing is attempted. The heat of plasticizing, usually from 350°F to 700°F, will cause any moisture present to vaporize. The steam and pressure generated will cause the plasticized material to foam or blister and will seriously affect the quality of parts as well as hamper processing it in the equipment.

The drying of granules is an easy, low-cost process. For short-run production the material is spread in one inch layers in trays and placed in a small heated oven with generous venting to the atmosphere. A typical drying period may call for two hours at 200°F.

Do not attempt to plasticize a material until the correct drying conditions have been met. The Plastic Properties Chart (Appendix III) contains drying recommendations.

Dry Coloring

Many plastic parts today are made in color. However, it is impossible to stock all available materials in a wide range of colors. Even the material manufacturers themselves usually stock in natural color: that is, the color which the processed granules have before any pigments are added. Many standard color pigments are available commercially. To obtain small quantities of special or custom colored material, a small percentage of color pigment, usually in powder granular form, is mixed with the natural granules. A typical situation might call for 2% by weight of pigment to be thoroughly mixed with granules. Any sealable container will do as a mixing chamber. A few minutes of active shaking will produce an adequate color blend. If colored materials are needed in substantial quantities, it is recommended the material be custom color blended by a professional coloring compounding service.

Pre-Heating

In the rare event that the plasticizing capacity (see below) of the molding machine constrains the rate of molding production, pre-heating may be useful. Since most thermoplastics are extremely sensitive to excessive or prolonged high heat, the material integrity can be protected by pre-heating the granules from room temperature to a point below that at which the granules become soft, before feeding the material into the plasticizing chamber of the machine. In this way, the amount of heat needed to complete the plasticizing is considerably reduced.

Plasticizing

The rate of plasticizing is an important consideration in a high-speed molding process. It becomes less significant and a minor problem in short-run applications; nevertheless, the method of evaluating the plasticizing rate can be helpful.

Plasticizing typically depends on the size and temperature of the melt cylinder, the type and grade of material being used, the starting temperature of the material, and the rate at which material is fed into the melt cylinder.

Molding equipment is rated in its plasticizing capacity by the ability to melt styrene measured in pounds/hour. The mathematics of plasticizing in a production cycle are straightforward. For example, assume that the time required to plasticize polypropylene in a melt cylinder at 550°F is three minutes. If the melt cylinder capacity is four ounces, then the plasticizing rate of the equipment would be 1⅓ ounces per minute. Production is then limited in continuous cycles to a rate not to exceed one shot of 1.3 ounce weight each minute, or.65 ounce every 30 seconds. Exceeding this rate will cause improperly plasticized material to be fed into the tool, and incomplete parts - or short shots - will result. By pre-heating the granules as previously mentioned the plasticizing rate can be increased.

Another variable condition which can change the rate of plasticizing is the melt cylinder temperature. For example, if a material has an ideal melt temperature of 400°F, the production rate can be increased by raising the cylinder temperature to 450°F. This change in melt cylinder temperature, to compensate for or to aid production rate increases, is normal in regular production cycles. It can also be a high risk venture. If, for example, the production rate was reduced and the melt cylinder temperature was not, the material in the cylinder would rapidly burn. Physical properties would be drastically reduced, colors would change and in many cases, fumes or toxic gasses would be generated. Some materials would pass through the range of normal melt and "best flow" conditions and tend to re-solidify. It can be difficult to purge this degraded material from the equipment.

Every thermoplastic material has a temperature range outside of which it will not process as desired. Low temperatures will result in short-shots and require excessive injection pressures. Higher than ideal temperatures will produce gassing, discoloration and impair physical properties.

For continuous good results, there is no better combination than an "average" melt cylinder temperature, properly dried and pre-heated granules and a steady non-fluctuating production rate. Establishing the values for these variables is a simple yet critical task. The first step must be to obtain constant extrusion.

Extrusion

The material granules fed into the top of the heated melt cylinder are compacted by the ram piston. As they move downwards towards the nozzle, they become plasticized. Ideally, the melt cylinder should be refilled after each shot, granules being fed into the top as the heated material leaves the nozzle. The small diameter ribbon of plasticized material leaving the nozzle is known as extrusion.

In order that the extrusion be in a condition ideal for injection, it must be correctly heated, free of blisters or gassing, free of lumps which would indicate unmelted granules and have a smooth glossy exterior. Use caution and wear protective gear when creating an extrusion. This molten material is under pressure and trapped air or gas may cause the material to pop and splatter when exiting the nozzle.

Before injecting a part of about one-half ounce, it is recommended practice to extrude a ribbon of this weight (or volume) from the nozzle. The extrusion gives immediate, visual evidence of the condition of the material prior to injection into a mold.

Injection

The act of injecting the heated material into a tool cavity usually requires considerable pressure. This pressure will vary dependent on the ease with which the material will flow, the size of the orifice through which it must pass, and the size or complexity of the cavity.

The variables to be considered in injection are the pressure and the rate of injection. Since correctly plasticized materials act typically as hydraulic fluids, for any given injection pressure the rate of flow will vary with the size of the orifice - or gate - between the nozzle and the cavity. If the gate area is doubled, the rate of flow will double. The cavity should be filled with material before the temperature drop caused by contact with the relatively cooler mold changes the material's flow characteristics. Material flowing into a tool will flow around both sides of any obstruction to meet on the reverse side of it. If the material temperature has dropped sufficiently, then the two fronts of material will not bond into each other and a weld-line develops in the part. Listed on page 101 are steps that can be followed to reduce or eliminate weak weld points (weld marks).

Naturally, each of these alternatives has both advantages and disadvantages. The material temperature can only be raised to the upper limit of the ideal range. A substantial increase in the mold temperature will reduce the rate of chilling and consequently slow down the production rate. Increases in injection pressure above that required to fill the mold will require additional clamping and part ejection pressure. An increase in gate size will leave a larger mark on the finished part. If the gate witness is not objectionable on the part, a gate correction should be the only necessary change to solve this problem.

Venting

As the material is injected under pressure into the tool, the air in the cavity must be allowed to escape to atmosphere. Any restriction to this escape of air will generate a back-pressure against injection causing a reduction in the rate of material flow and encouraging air entrapment within a part. It can also contribute to incomplete or short shots in the cavity.

It is customary to vent the mold at the parting line. That is, cut air vents from the edge of the cavity to the outside of the mold. A typical vent would be .003 inches deep and ¼ inch wide. The vents should first be located at the extreme corners of the cavity farthest from the gate. If during sampling one or more areas of a cavity tend to underfill - as indicated by short-shots or knit-lines - these areas should be vented. If a vent is too deep, a small amount of flash will tend to appear on the finished part. Over-venting is always preferable to under-venting since the flash is easily removed in a secondary operation. An unvented mold is an incomplete mold.

Sprue, Runner and Gate

After leaving the nozzle and before entering the cavity, the material must flow through one or more passages in the tool. The first of these, which leads directly from the nozzle is a tapered passage running in line with the melt cylinder towards the center of the mold. This is the sprue. Its function is to guide the material directly to the mold parting line. In low-cost tooling designed and built for prototyping or short-runs, the sprue may run directly from the nozzle to the cavity (see page 44). It may be tapered in either direction, so that the large end is open to the cavity, or so that the large end is adjacent to the nozzle and the small end connects to the cavity via a gate (see page 36). It is always tapered so that the part and other material, once chilled, can be easily removed.

When the large end of the sprue is adjacent to the nozzle, it is normal to place a nozzle adapter between the mold top surface and the nozzle. The adapter has a conventional ball seat with some flow grooves and a tapered short sprue. After chilling, the sprue may be removed from the mold by simply rotating the adapter which breaks off the sprue at the gate. A light tap on the bench top will eject the sprue from the adapter. Naturally, the hardened steel adapter also protects the top surface of the tool from damage or wear.

In tools where more than one cavity exists, or in some three plate tools, the material must be guided by runners from the lower end of the sprue to the cavities. It flows along, or parallel to, the tool parting line at right angles to the sprue. The runners should be as short as possible with a minimum of turns or corners. A good runner has a circular cross-section since this gives the lowest area of exposure to the cooling effects of the mold. A half-circle or flat, ribbon type runner is bad practice.

A gate is located between the runner and the cavity. This gate is a small orifice through which the material must flow to enter the cavity. The gate may be round or rectangular. Typically it will be as large as aesthetic considerations will allow. If the part to be molded has a wall thickness of .06 inches, the gate should be at least .06 x .06 inches square or an equivalent area if round (approximately .09 inches diameter). The gate should be as short as possible and never longer than its diameter or square size. Once again, half-circle or flat, rectangular gates are not desirable.

Chilling and Tool Temperature

The temperature at which a tool is maintained is always a compromise. A cool mold allows fast chilling of the material and higher production rates. However, if the material is cooled too quickly, poor surface finishes are obtained. Often a "rippled" finish or "orange-peel" effect will result on the part. Premature freezing of the gate can cause short-shots, knit-lines, and excessive sink. Under this condition, material temperatures must be higher than ideal and higher injection pressures are often required to give an injection rate fast enough to fill the mold before the material chills.

Conversly, an over-heated mold will cause extended chill times and resultant long cycles. The part when finally removed from the tool will still be hot: subsequent cooling outside of the cavity will cause distortion and reduce dimensional stability.

A fluctuating mold temperature will cause variations in part quality and size. Within the closed mold, shrinkage is restricted, and so parts leaving the mold at different temperatures will have different amounts of shrinkage.

As a cool mold is run, it tends to increase in temperature. However, with each successive shot, the rate of temperature rise is reduced until after some period of time the mold temperature will stabilize. Heat loss to atmosphere will balance heat gain from the material injected. With short-run tooling (usually aluminum) the temperature will stabilize well below that which will cause part distortion. Parts made on the tool before the stabilized temperature is reached will all be subject to size and quality variation.

To eliminate this problem, a pre-heat plate is recommended. This heater will quickly raise the mold to correct working temperature and will maintain this temperature throughout the day. (See the Plastics Properties Chart for recommended tool temperatures.)

Cycle Time

All thermoplastic materials are sensitive to heat. Because of this, the rate at which they can be plasticized is limited. Once plasticized, they may be maintained at this temperature for relatively short periods of time. Improperly plasticized materials cannot be successfully shot; over-heated materials will degrade and discolor.

As a result, the material should be kept moving through the machine at a relatively constant rate. It is therefore essential to establish a regular cycle of operation. The time interval between shots must allow for a thorough melt, and yet prevent burning. Naturally, the melt cylinder temperature can effect this time, as can the type of material. Typically for prototype and short-run molding, cycle times will vary from 30 seconds to 10 minutes, depending on the shot size, the amount of material to be plasticized between each shot, the material heat tolerance and mold handling requirements. It is most important that, once established, the time interval between shots is held fairly constant. Use a clock or a timer to regulate the cycle.

Establish a cycle time which will allow a good shot each time and will maintain a desired mold temperature. If testing indicates that a material will plasticize at a rate of 4 ounces each 5 minutes in the machine, it is far better to set a production pace which will use only three ounces in five minutes. This way the material will always be thoroughly prepared. This is consistent with the principle of designing only up to about 80% of rated capacity. The apparent loss in capacity will actually pay off in reduction of scrap parts, and production of parts with consistently good dimensions and surface finish.

Ejection

When chilled - usually about 10 – 15 seconds after injection is complete - the part should be removed from the tool in such a way as to avoid any damage. A number of mechanical methods are used and each method has one factor in common. When the material cools, it shrinks away from the outer cavity and on to any internal insert or core. Hence, when the tool opens, it is possible to accurately predict on which side of the tool the part will be found. The ejector system must be designed to push the part off the core (see pages 38 & 84).

In conventional production tools, ejection is performed by a pattern of ejector pins in the mold base. These are attached to a moving plate which is forced upwards after the mold is opened (see page 96). In prototype or short-run tooling, a threaded core is often left loose and can be removed from the tool with the part molded around it, the part is then unscrewed from the core (see page 44). An ejection slip ring (see page 38) that is lever activated is another prototype technique for loosening or "stripping" parts off of a core.

Another well-proven method is to leave the sprue attached to the part and use this to pull the part from the mold (see page 66). If a reverse tapered sprue has been used, it is often possible to open the mold with the sprue still attached to the part and thus ensure that the part is withdrawn from the mold (see page 36).

To avoid any damage to the core or cavity in aluminum tooling, always use a plastic or wooden device to pry the part loose. When the sprue is attached to the part, the sprue can be pulled with pliers since it will be discarded.

CHAPTER TWO

TOOL DESIGN AND BUILDING

There are three distinct types of tooling in everyday use. They are identified by their method of usage, their intended life, and their cost.

HAND MOLDS

The hand mold is usually a low cost, simple tool which is placed in the injection press, clamped, filled and then removed by hand to be opened on the work bench for removal of the molded part. Typically, production rates run to a maximum of 80 parts per hour. The tool consists of a few simple aluminum parts, each a functional part of the core or cavity. Tool life is usually measured in the hundreds of parts. The hand mold is used when part quantity requirements are low, and tool cost is more important than part running cost. In correctly made aluminum hand molds, the part quality and finish can be as good as from more expensive steel tooling.

SEMI-AUTOMATIC MOLDS

In this type of tooling, the upper or hot side of the mold is attached to the molding machine so that the nozzle and nozzle seat are adjacent. The sprue must be conventional in that it tapers to increase as it moves away from the nozzle. The base or core side of the mold is bolted directly to the machine table. Either a hand-operated or semi-automatic ejection system will aid in removing the part from its cavity. As the molding machine operates the mold is clamped, filled and opened. An operator is required to remove the parts and cycle the equipment. This type of tooling is used when part quantities tend toward the low thousands. The production rates would typically be 100 to 180 parts per hour depending upon the shot size and the material being processed. Once the equipment is set up, semi-skilled labor can be used to operate it. Tool materials would normally be aluminum with beryllium copper or steel inserts. Tool life is typically in the 10,000 shot range; this can be significantly extended by use of finishes such as hard anodizing or chrome plating, or use of steel cavities and cores.

This type of tooling is extensively used for short-run applications. Part costs are often a small fraction of the costs of fabricating by other methods and quality can be every bit as good as from full production tooling.

AUTOMATIC MOLDS

Since this type of tooling is used when production quantities are large and piece price is of supreme importance, discussion here will be limited. Tools are usually of heat treated steel, ejector systems are automatic, and mold heating and water chilling systems are added. In some instances, when a moderate quantity of parts is urgently needed and production equipment is not available, this tooling can be fitted into and run efficiently in a Morgan-Press. An operator will be required to cycle the machine and feed in the plastic materials. The smallest Morgan-Press (Model G-55T) can sustain production rates of 180 cycles per hour on four-cavity molds with shot sizes from 5 to 10 grams. The cost of set-up and production of a few thousand parts can sometimes be less than the normal "set-up" charges for automatic production equipment.

TOOL QUALITY DESIGNATIONS

Tool quality can also vary, depending on the need for parts. The requirements for quantity, quality, dimensional accuracy, surface finish and materials to be molded can drastically affect the required quality (and cost) of the tooling to be built. In order to define tool quality simply, it is designated Class C, B, or A. These classifications are not intended strictly as an evaluation of the workmanship involved in tool building, but rather as an indication of expected tool life.

Most hand molds would be designated Class C. The design, use of materials in the tool and total tool building time would reflect the need for economy due to small part quantity requirements. Rather than complicate the tool to develop very fine tolerances or intricate detail in the molded parts, the parts might be subjected to secondary machining operations after molding. It would obviously be better to drill and tap a #10-32 cross-hole in 50 parts, an hour's work at most, than to spend four hours making and fitting a rather delicate core to the tool. Every tooling decision must be made with economics in mind. The objective becomes to achieve the lowest possible total cost of producing the tool and the required molded parts. Since the hourly labor cost for operating the molding equipment will be less than the hourly costs of a machinist or toolmaker, the decision will usually be to reduce tool building time and to increase molding and post-mold finishing time.

A Class B tool would typically have more informal detail, be made from more expensive or harder-to-work materials, and be intended for semi-automatic use. The increased mold making labor would be justified by higher parts production, faster production rates and fewer secondary finishing operations. Tool cost is, however, still a significant consideration. Cross-holes in the part are produced by hand-pulled cores or loose inserts. Internal and external threaded cores or inserts would be hand-rotated. Tools may contain engraving, surface texturing, polished and plated sections. The mold may have more than one cavity. One Class B mold is an excellent, low cost short-run production tool.

Class A tooling is produced with extended life, speed of operation, and part costs as prime considerations. It is used in short-run situations only as a stop-gap measure, usually for pilot or sample production. There is no such thing as low cost Class A tooling. To produce Class A Tooling requires the services of experienced designers and toolmakers using the finest materials. There are many fine tool-making shops ready and willing to quote and build Class A tooling to your needs.

The object of this book is to help you to become proficient in the design and building of Class B and C tooling, using limited resources and knowledge. With proper engineering help and encouragement, anyone with a knowledge of drafting or machining can produce perfectly acceptable Class C tools. With the use of a Morgan-Press, these tools will produce valuable and competitively priced molded parts in short-run quantities. Many companies have found that in an extremely short period of time, they were producing good Class B tooling. The examples illustrated in Chapter V are typical of the tooling produced by machinists previously inexperienced in toolmaking.

MAKING THE TOOLING DECISIONS

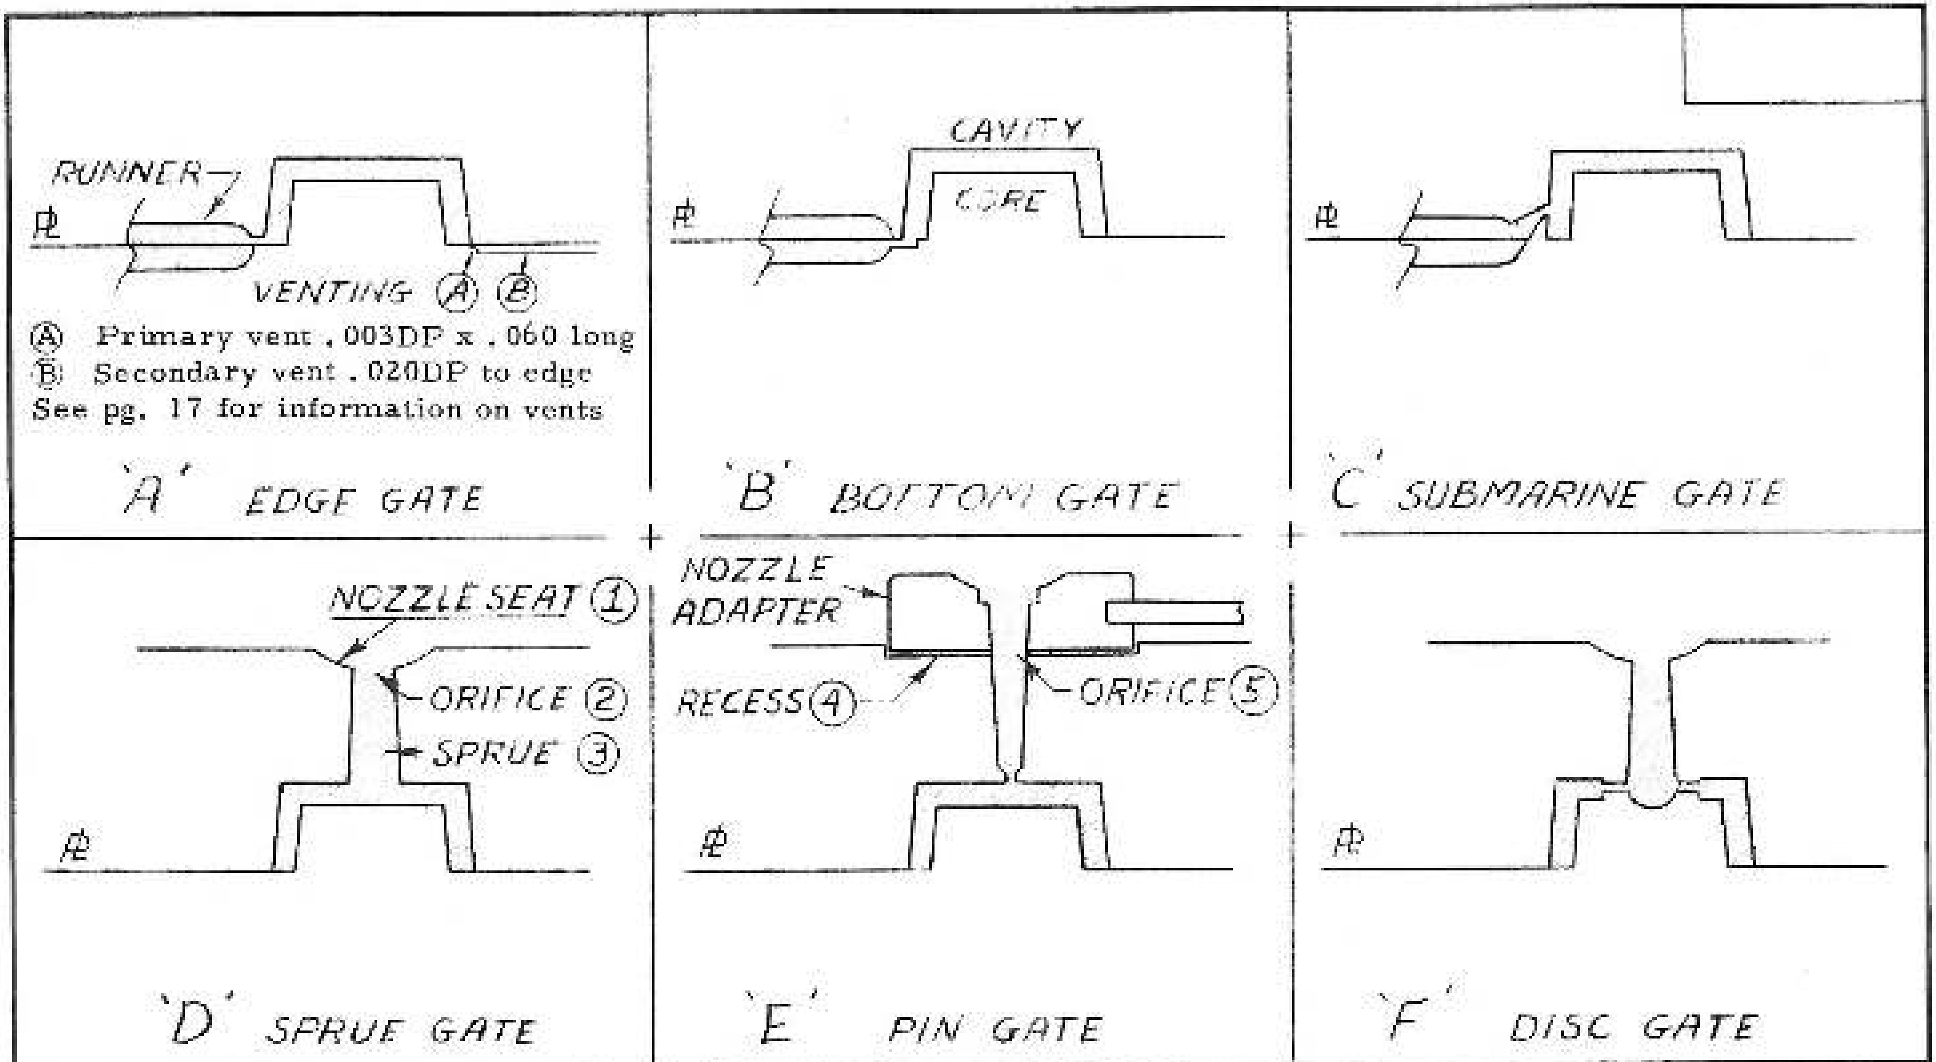
By using a simple format to notate the information relative to a part, it is possible to make a quick, accurate judgement of the required tooling. When in doubt, make a single cavity Class C tool and gain experience. If necessary later, upgrade the tool to Class B or make a multi-cavity Class B mold.

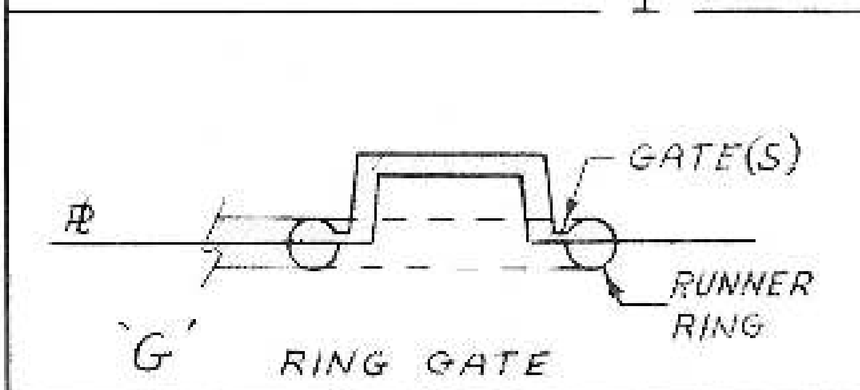
	TOOL		
PART	**Class C**	**Class B**	**Multi-Cavity Class B**
Part design firm and proven	No	Yes	Yes
Part material firm and proven	No	Yes	Yes
Post finishing required or acceptable	Yes	Slight	Minimal
Quantity requirements - Total	To 500	To 5,000	To 25,000
Finish requirements - as molded	Open	Good	Good
Part cost allowance	Over 50¢	Over 25¢	Under 25¢
Toolmaking skill available	Slight	Moderate	Moderate

MOLD DESIGN

Having decided on the type of mold required, the next step is to prepare a design for the shop.

On the part drawing, mark any details which can be produced by secondary operations. Next, trace the part outline on paper to determine the location of a parting line for the tool. The main parting line is generally located at the part's largest cross-section. With a cup shaped part, for example, the parting line would be at the rim of the open end. The cavity side of the mold - the hot side - which houses the sprue would have in it a recess the size and shape of the outer contour of the cup.





TYPICAL SPRUES, RUNNERS, GATES + VENTS

NOTES:

1. Nozzle Seat--1/2" radius x 1/8" deep
2. 7/32 Dia. for 'B' Nozzle & Anti-Drool Nozzle
   5/32 Dia. for 'A' Nozzle
3. Sprue Taper--3° to 5°
4. Nozzle Adapter Recess--1.520 Dia. x 1/32 deep
5. Mold Orifice for Nozzle Adapter .230" Dia.

The core side - the base - would have a protrusion on it the shape and size of the inside of the cup adjusted for anticipated material shrinkage. When placed together, the mold halves would be in contact all around the parting line and have a gap between the core and cavity equal to the wall thickness of the cup.

Refer to the illustrated examples of mold design in Chapter V. It is most probable that an illustrated idea, or a combination of ideas from one or more of these examples will provide you with a basic design to follow. The mold should be drawn so that each part is rendered from a simple machined block, manufacturable by an available machinist. To eliminate the necessity for many tight tolerance dimensions, also show an assembly picture, indicating only the basic outside sizes of the mold and the required fits (e.g. drive fit dowel or .001" oversize ream for a slip-fit or .005" clearance for a free fit).

Whenever possible, use standard sizes for the materials from which the mold is to be made. Quick reference to a material stock list will provide a wide assortment of materials and sizes. A mold must be designed so as to withstand pressure from clamping action of the machine and also pressure from within during injection. These pressures can be quite high. Clamp pressures of up to 20 tons can be achieved on a Morgan-Press and internal pressures up to 13,500 psi or <u>6.75 tons per square inch of mold surface area</u>. When designing aluminum molds, it is essential that a wall of at least one inch of metal remain outside the cavity. For a 1 inch diameter cavity, use at least a 3 inch diameter bar stock or square block. When milled cavities are of 1 inch depth, use at least a 2 inch thick plate. When semi-automatic tooling is to be built, use much larger material sizes so that the extra heat involved can be absorbed more evenly and be dissipated from the enlarged area. Additionally, the material has to be large enough to mount in the machine as well as accommodate ejector systems that may be built into the tool.

GATING

Two main factors influence gating: gate location and gate size. For symmetrically shaped parts such as gears, discs, cams, and plates, the gate should be as near the center as possible. With a gear, for example, gate into the center hole or disc gate as shown on page 46. For sections which are cup-shaped, sprue gate as shown on page 12, or reverse sprue gate as on page 36. Avoid gating into a thin wall section. Gates should always allow material to flow into the heaviest section of a part first if at all possible. If necessary, make a heavy section on the part to gate into, then machine away the excess material later. The function of a gate is to allow material as quickly as possible into the mold and produce even filling of the cavity with moderate injection pressure.

The material to be used can influence gating significantly. For vinyl, which flows freely when plasticized, a half-ounce part might typically require a .09" diameter gate. The same part from Noryl would need approximately twice the gate size.

* * *

To summarize the subject of tooling design, it is strongly recommended that these decisions be carefully planned around the following factors:

- Anticipated life of tool; quantity of parts required
- Selection of tool material
- Aesthetic requirements of part affecting selection of gating and parting line
- Critical dimensions of part; their relation to other parts in an assembly
- Plastic material selection for part

TOOL BUILDING

There are a number of methods in use for manufacturing the parts of a mold. Besides various techniques for making the cores and cavities, there is a need to create gates, vents, sprues and establish the proper fits, clearances, and drafts in the tool.

The core or insert, being a male form, is usually turned on a lathe or milled from plate or bar-stock material - or a combination of both. The cavity, however, being basically a recess, can present some problems. A round cavity is simple, and a rectangular cavity, providing it can have radiused corners, is easy to mill. However, a rectangular cavity with sharp corners all around is impossible to mill.

One method of producing a cavity with sharp corners is to machine mold inserts as shown on pages 42 and 90. Alternate, often more desirable methods of producing these sharp corners, as well as other complex configurations, include EDM'ing, hobbing and casting.

COMPUTERIZED MOLD DESIGN AND CNC MACHINING

There are a side variety of computer programs for enabling engineers to create designs for both their parts and mold layouts. These designs, in conjunction with CNC programs for machining equipment with the proper controls are significantly simplifying the mold making process for the modern engineer with computer skills.

EDM (Electrical Discharge Machining)

EDM (Electrical Discharge Machining) operates on the principle of removing metal with electrical energy. An electrode having either a male or female shape designed to produce a corresponding cavity or core is positioned into the EDM machine. The electrode is then lowered into a work tank filled with dielectric fluid and to within a few thousandths of an inch of the work piece (mold plate). Electric arcs traveling across the gap then "cut" away the cavity material.

The electrodes are commonly made of EDM graphite, brass, or other conductive alloys such as copper, silver and tungsten. The electrodes must be dimensioned to compensate for the overburn (spark gap) which occurs during the EDM process and also to allow for the plastic shrink factor. For very complex mold cavities or where several of the same electrode are required, electrodes can be purchased from companies which specialize in producing molded electrodes (usually copper tungsten) from models of the finished parts.

Any conductive material or metal - tough, hard, soft, brittle - can be EDM'd. Many conventional machining applications are now being replaced by EDM because it is more accurate, more reliable or more economical. Also configurations that were thought to be impossible or very difficult to machine a few years ago are now being produced by EDM. Micro slots, burr-free holes, intricate dies and contours make excellent EDM projects. The recessed contours and square corners as the example in page 96 is an ideal EDM application. For difficult shapes in carbide, exotic metals, hard or soft tool steel, aluminum or other conductive materials, nothing matches the economics of electrical discharge machining.

Hobbing

To produce this cavity, it is necessary to produce a male form in steel with the shape of the desired cavity (see page 36). The hob was lathe turned to the required diameter, then milled to produce the external ribbing. The hob of oil hardening drill rod was then hardened by heating and quenching in oil. Next the cavity was prepared for hobbing by being lathe turned to the size of the hob at the bottom of the ribs. Finally, after being generously coated with white lead - an effective non-galling lubricant - the hob was forced into the cavity in a hydraulic press. It could equally well have been impacted into the cavity. It is possible to hob cavities in aluminum, kirksite and soft low-carbon steel.

It is normal practice to hob a cavity to an over-depth condition. If a cavity must be finished to .500" depth, the hob should be forced into a depth of .530" and then the parting line of the cavity should be machined or surface ground down .030".

Casting

This same over-depth requirement exists when a cavity is to be cast. First, a model is made of the required part with the dimensions suitably increased to allow for shrinkage. From the model, a pair of epoxy or silicone rubber molds are cast. From these molds, plasters are cast and thoroughly dried by baking at 250°F for some hours. Finally, aluminum or kirksite is poured into the plasters and the resulting cores and cavities will be a fine detailed reproduction - in reverse - of the original model. This method of producing molds is used when the article to be reproduced is difficult to duplicate by machining as for example a sculpture or carving.

Please refer to the chapter on Epoxy Tooling for a complete and detailed description of low-cost casting techniques.

Fits and Clearances

When plastic is forced into a mold, considerable pressure is involved. The material will flow into all fine corners, edges and cracks. Any space of .003" and greater will tend to become filled. If a clearance of .005" is allowed between a recess and the insert in it, the space will fill with material.

It is essential in producing a good mold to carefully size and fit all internal parts. For slide-fit dowels or ejector pins, use a reamer that is size plus .001" or .002".

Draft

When machining a cavity or core, always use a tapered mill cutter or lathe turn with the compound slide set at an angle. The cavity must decrease in size as it moves away from the parting line. A core must decrease in size from its base toward its highest point. The draft in a cavity must be at least ½° per side; the core should be drafted a minimum of 1° per side. Remember, the part will shrink away from the cavity and onto a core or insert (see Appendix I for Draft Angle factors).

Location of Mold Sections

In order that the desired accuracy be maintained in a part, it is necessary to locate the mold sections relative to each other. In lathe turned molds, location diameters can be machined during the making of the tool (see page 54). Molds made from square or rectangular plates are aligned by doweling the two matching pieces. See page 90 for an example of Leader Pins that locate the 'A' plate with the 'B' plate. The drilled and reamed holes should be a close fit to assure proper alignment and prevent any binding. Next, finish the side walls of the blocks to establish good edges that can be used for marking out the cavity. This preparation is a necessary step and will subsequently result in more accurate cavities and finished parts.

Any of the following operations will aid in relocating the mold halves: use different size dowel pins, stamp alignment marks or mill flat one corner (see example on page 66).

Gates

The gate should be cut only after the cavity and core are completed. Start small and increase the size until no signs of knit- lines remain in the molded part. A large gate will produce a better quality part than a gate which is too small. Refer to page 12 for examples of various gate designs for different molding purposes.

Sprue

The size of the sprue at the nozzle end must be larger than the size of the nozzle orifice. Typically for a 3/16" diameter orifice nozzle (B size) the sprue orifice would be 7/32". The next most important item is the finish of the sprue hole itself. It must be smooth, free of chatter or scratches. Practice has shown that it is best to finish the hole with a straight flute hand reamer. Most local industrial tool suppliers offer tapered reamers in various sizes suitable for sprues.

Vents

One of the most important features of a tool is the vent system. Air must be allowed to escape as the material enters the cavity. Vents should be cut at the parting line in various locations around the cavity. See page 12 example 'A' and page 90 for vent design and dimensions. Occasionally it is necessary to vent a large cavity at locations other than the parting line. Core pins and inserts can be designed to provide this added venting.

If during sampling, it is found necessary to increase the gate size, it should also follow that the venting may have to be increased. The width and number of vents is determined by the size of the cavity and the rate of fill. Over-venting is rarely a problem since the resulting flash on the molded part can easily be trimmed; underventing is a common fault.

Tool Size

The size of the part will regulate to some extent the size of the finished tool. The mold surface at the parting line should be at least one inch larger all around than the part size. The plate thickness should be no less than one inch greater than the maximum cavity depth.

When mold halves are to be bolted together, use ½"-13 bolts. Small bolts tend to shear or have the threads strip. Bolts should be positioned symmetrically around the sprue, three for a round mold, four for a rectangular mold.

TOOLMAKING MATERIAL

Aluminum

The most widely used material for prototyping and short-run tooling is aluminum. It is readily available, lighter to handle than most other metals and machines easily. It will take and hold a high polish, and the harder grades wear well. It is resistant to corrosion by most plastic resins and the fumes that they may generate. Aluminum is not highly resistant to erosive or abrasive effects; however, it will easily take hard chrome plating or hard anodizing as surface finishes. These finishes are necessary when parts are needed in such materials as glass-filled nylons which are abrasive. Aluminum grades typically used for tooling are 2024T4 or 7075T6.

Beryllium

This is a copper based alloy with a hard, low-friction surface. It will machine and polish well and is highly resistant to abrasion. Because of its high cost, it is used mainly for inserts or cores where aluminum does not have sufficient strength. It requires no heat treatment. Some molding compounds, especially those with chlorine content such as vinyl, may cause rapid corrosion to beryllium. Beryllium may also require special handling during machining due to fumes emissions.

Kirksite

This is a low-melting point, non-porous alloy, rather soft and free cutting. It will cast easily capturing fine detail and is usually used to produce molds of sculptured or detailed parts. It may be cast into well-dried plaster molds. The resulting castings are used as molds for plastic molding. Mold life may be extremely short, often well below 100 pieces; however, the mold can be easily made without intricate machining.

Steel

When strength, resistance to wear, and resistance to accidental damage are factors, steel is an obvious choice of mold making material. Tool steel is easy to machine, readily available, inexpensive, and can be moderately case-hardened at a minimal cost. Sprue bushings, cores, inserts and thread forms can be made easily in tool steel and then case-hardened if necessary. To avoid the problems of heat treatment, tool steels or drill rod are highly recommended. These materials, although partially hardened, can be machined and polished and are favorites for sliding cores and loose inserts. Large hand operated molds should not be made out of steel due to the weight. A steel plate that is 5" x 6" x 2¼" weighs 20 pounds. A piece of aluminum the same size is only 7 pounds. In many applications it is better to have an aluminum mold base with steel inserts for ease of handling.

Other often used materials come in the form of ready-made components. They include hardened steel dowels used for location pins and cores, and ejector pins which are available in many sizes and may also be used as core pins.

MOLD FINISHING

Every mold, core or cavity requires some finishing. First and foremost among the finishing operations is polishing. The idea here is to have a smooth surface as well as high lustre on the mold working surfaces. First, all machining marks must be rubbed away, and all undulations or ripples in the metal surface removed. Only then will polishing be effective. The tools used are as follows:

> For removing rough machining marks, lightly sand with emery or carborundum cloth. Next, rub with a rough polishing compound (approximately 280 grit) on balsa or hard wood sticks. Felt pads used in motorized hand tools can also be used with compound. For a finer finish, use a 600 grit compound finishing with a metal polish on cloth. Remember the molded part appearance will be no better than the surface finish of the mold cavity and core. Polishing may account for 10 to 15 percent of the total mold making time.

Protective coatings such as chrome or nickel plating, hard anodizing or case hardening should only be applied after thorough polishing. Likewise, surface texturing, for example, and blasting to remove lustre, or photo-etching to produce a pattern, must be applied over a smooth surface to achieve the desired quality.

CHAPTER THREE

PART DESIGN AND MATERIAL SELECTION

When designing a part for injection molding, the method of toolmaking becomes an important consideration. It is the designer's responsibility to consider the alternatives and produce a design which is moldable using conventionally made toolings.

First, break down a part into simple components. Two or three simple pieces are often easier to tool than one complex part. The parts can be assembled easily together using snap-fits, solvent bonding, ultrasonic welding, as well as conventional use of rivets, eyelets, screws, etc. When quantities are not high, the assembly labor will be more than justified by the savings in tooling cost.

The most significant rules in part designing are <u>keep the wall sections constant</u>, and <u>use adequate draft on all vertical surfaces</u>. Indicate on the part drawing the location of the parting line. Show clearly the direction and angle of draft on the inside and outside faces. If a situation calls for "no draft" on a part, have extra material on the part and mold it with draft. Use secondary operations to remove the excess material and generate the parallel surfaces.

Wall thicknesses on molded parts are typically from .03" to .100". Excessive pressures are needed to push material into cavities with less than a .03" wall. Sections over .200" will tend to cool too slowly and stresses and sink marks will result.

It is bad practice to have extremes of thickness or localized heavy sections on a plastic part. Differences in cooling and chilling rates will invariably cause warpage in the finished item. When a heavy section must exist, use it as filling point for the cavity. Gate into a heavy section if possible; try never to fill a heavy section from a thin section.

The best possible source of information for the plastic parts designer is to study ready-made parts in the office, stores, and home. Examine the parting lines, drafts, gates, ejectors, surface finish and try to judge the material. Probably the most critical decisions facing the designer are establishing acceptable tolerances and selecting the material. To a great extent one will affect the other and both can significantly affect costs.

TOLERANCES

The most common error made by designers using plastics is to call out tolerances normally found in metalworking. The skilled toolmaker can cut cavities and cores in metal as accurately as any other fine machinist; but as in other industries, close tolerances cost money. Once the mold is made, the parts coming from it will not all necessarily be the same size.

All plastic materials will shrink when cooled from a plasticized semi-fluid to a chilled part. The shrinkage will depend on the mold temperature and the material temperature change. If a cavity is cut exactly four inches long at 70°F, then is heated during the molding process to 200°F, it will increase in length and so will parts molded in it. If the mold expands .005" in length, the minimum part variation will be greater than this. If in the same mold, a part is shot at 500°F and another part is molded from material plasticized at 600°F, the parts will vary in length due to shrinkage factors. Indeed, parts will actually shrink on a three dimensional basis thus creating even greater potential for tolerance variation.

A third factor is the variation in material shrinkage even when the plasticizing and mold temperature can be held constant. These changes can be the result of ambient temperature or humidity fluctuations, or of changes in injection pressure and speed.

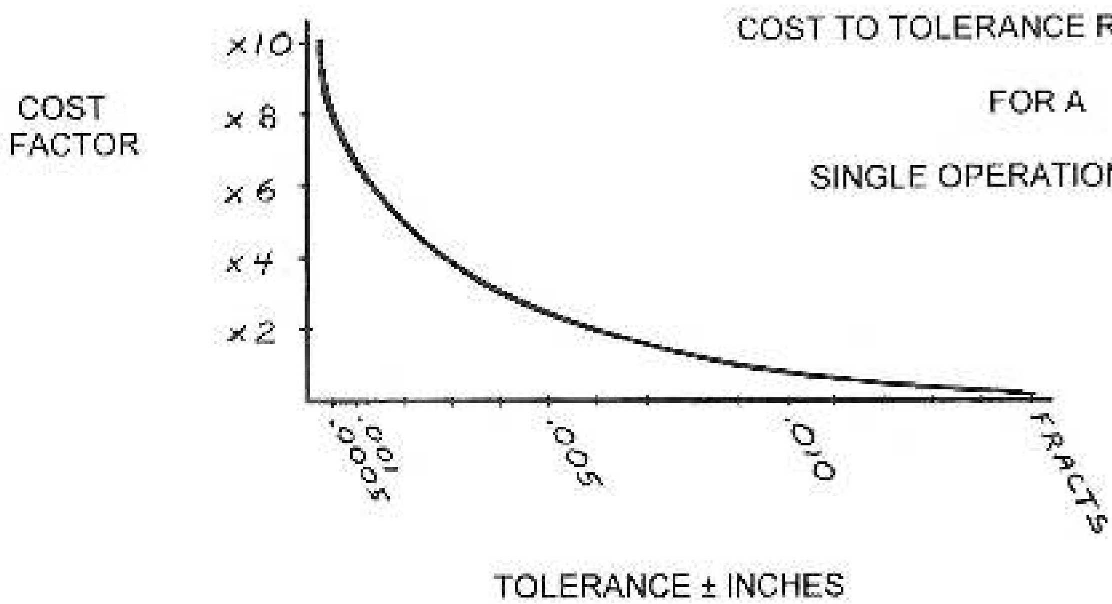
When a machinist is to cut a cavity, he must <u>estimate</u> how much oversize he must machine to allow for shrinkage. This shrink allowance can vary from .002 to .004 inch per inch for materials such as polystyrene up to .020 to .025 inch per inch for different grades of acetals. It is not reasonable to demand a +.000 -.005 tolerance on an inch since this leaves no latitude at all for the toolmaker or molder. Close tolerances can be achieved in plastic but only if mold dimensions can be adjusted after the mold is sampled. This way actual shrinkages are established and the process variations can be held to tighter limits. (See Appendix II for machining shrinkage factors.)

Many studies have been run to establish the relationships between tolerance and cost. The results of one such study are graphically displayed below. Plastics are almost always used to reduce manufacturing costs in a product. Only careful designing and critical study of actual tolerance requirements can maximize these savings.

COST TO TOLERANCE RELATIONSHIP

FOR A

SINGLE OPERATION SET-UP



THERMOPLASTIC MATERIALS

The physical properties of injection moldable materials vary from the soft flexibility of gum rubber to the brittleness of glass; temperature resistance varies from complete softening and dissolving in hot water to an ability to withstand a brief exposure to flame. Costs vary from a few cents to several dollars a pound. (See Appendix III for physical properties and cost per pound.)

The decision as to which material to use for an application need not be a difficult one since over ninety percent of thermoplastic parts used are made from no more than a dozen basic materials. Often a part can be successfully made from any one of a number of available materials. Listed below are the most commonly used thermoplastics with a brief description of their most notable characteristics and uses.

A.B.S.

A.B.S. is a copolymer - a mixture of acrylic (which gives it a high lustre and hard surface), butadiene (a rubber which adds impact strength), and styrene (a rigid, low-cost base). Telephones, typewriters, instrument cases and household appliances are made from A.B.S. It colors well, resists staining and solvent bonds easily. Low cost.

Acetal

Parts which must maintain a springiness such as latches and snap catches are usually made of acetal since it strives to retain its molded shape. A low co-efficient of friction, good wear resistance and rigidity make it excellent for bearings and gears. It has excellent resistance to chemicals. Medium cost.

Acrylic

This material has good optical clarity and is available in brilliant, transparent colors that are stable against discoloration. Its glossy surface and high-impact strength is resistant to outdoor weathering. These characteristics plus excellent electrical and heat properties make this material widely used for light control lenses. Medium cost.

Nylon

As any ardent fisherman will know, nylon is a tough material with a high resistance to abrasion. It tends to be self-lubricating and is used extensively for bearings, gears and wear surfaces. Nylon is resistant to common solvents. Molding is made more difficult by the material's narrow processing temperature range and its extremely high moisture absorption rate. Medium cost.

Phenylene Oxide

This is a high-temperature resistant material used for electrical components such as switch housings and junction boxes. It is hard, wears well, and will solvent bond. High cost.

Polycarbonate

This material is extremely tough. Impact resistance is its real asset although clarity and surface lustre make it a favorite for appliances such as electric drill housings and handles for kitchen appliances. Windows and lenses are often molded of polycarbonate particularly for non-breaking uses. Polycarbonate will solvent-bond readily. High cost.

Polyester

Polyester is dimensionally stable and has low moisture absorption. It has excellent resistance to a broad range of chemicals such as gasoline, alcohols and dilute acids and bases. Many parts requiring impact strength, smooth surfaces and good wear properties are made of polyester. Medium cost.

Polyethylene

Many food containers used in the home are polyethylene. So are many toys and utensils. The material will float on water, has a waxy feel, scratches easily and resists most solvents, chemicals and detergents. It molds easily at low temperature, has high dielectric strength. Low cost.

Polypropylene

This is the lowest density common plastic. It floats easily, can be sterilized by boiling, has a high lustre surface, molds easily and is fast replacing other plastics in the electronics industry as a component material. It will not absorb water, and it resists most chemicals and solvents. It is flexible, but has poor wear resistance. Hinges molded in polypropylene will frequently exceed one million flexings without failure. Low cost.

Polysulfone

Polysulfone is strong, rigid and has a very high heat-deflection temperature along with excellent electrical properties. It is toxicologically inert, resistant to stain, taste, odor and a wide variety of chemical compounds found in food and medical environments. High cost.

Styrene

Styrene varies from a crystal clear, brittle material used for cosmetic containers and transparent boxes for low-cost jewelry items to flexible, high impact colored plastic used for toys and low cost containers. It has low resistance to chemicals and heat, will solvent bond easily. Low cost.

Urethane

The wear resistance of this material is often many times that of rubber compounds, and it resists oils and many chemicals. Usually rubbery in feel and flexibility, its uses include noise-free, long-wearing gears and drive belts, electronic encapsulations, shoe heels and impact or shock pads. High cost.

Vinyl (PVC - Polyvinyl Chloride)

Most electrical wire coverings and plugs are made of vinyl. It is the most widely used encapsulation material for injected electronic components. It molds easily at low temperatures and will reproduce fine mold detail. Most vinyls are heavily plasticized by the addition of oil-like materials. It has poor temperature resistance and if over-heated, it discolors, can disintegrate and emit chlorine gas. Vinyl can be solvent-bonded but has low chemical resistance. Low cost.

FILLERS AND MODIFIED MATERIALS

In order to improve or change the physical properties of thermoplastics, other non-thermoplastic materials are added to the granules by the materials manufacturers. Some of the most common fillers and their values are discussed briefly below:

Glass

Fibers of glass, similar to glass cloth, are mixed with many materials such as nylon, phenylene oxide, and polypropylene to increase the material strength. Percentages are from 10 to 40% of the filler. Both impact and heat resistance are greatly increased. Moldability is often improved by the glass because it acts as a good heat carrier, speeds plasticizing and aids flow into thinner sections. Gate sizes may need to be increased especially with the higher fill percentages due to higher viscosity.

Glass beads are also being used as a bulk filler and cost reducer in some more expensive materials. Surface hardness is increased and shrink rates are considerably reduced. The glass particle sizes are extremely small so gate sizes are not affected. Moldabilty is often improved - especially with nylons.

Lubricants

For the production of parts subjected to high wear or abrasion, lubricants such as powdered teflon or molybdenum disulfide (MOS) are added in small quantities. Percentages would typically be from 2 to 5%: wear resistance is increased, and since the lubricant is impregnated into the part, external lubrication is often avoided.

Carbon Fibers

Thermoplastics that are fortified with carbon fibers have a strength and modulus value similar to die-cast alloys. The strength, lubricity and conductivity of carbon-filled materials has opened doors for plastic applications not previously possible.

Plasticizers

Some materials, such as vinyl, are naturally hard and brittle.

To make such materials flexible and soft, oil-like chemicals are added in quantities from 5 to 30%. A normal plasticizer is D.O.P. di(2-ethylhexyl) phthalate which will attack some thermoplastic materials. Styrene should never be used in close contact with vinyls containing plasticizers unless considerable product testing is first done to evaluate any possible problems.

Other fillers commonly used include chalk, wood flour, titanium dioxide, ceramics and metallic powders. The material suppliers' specification sheets will give full details on fillers and material properties.

* * *

Materials such as polypropylene and polyethylene are known as homopolymers since each is a pure polymer. When these materials are mixed by the materials manufacturer during processing, the resulting blend is known as copolymer. This term denotes only that the material is a chemical blend and has physical properties resulting from both parent materials.

The material manufacturer can modify the physical properties of materials by changes within the formulating process. Such changes are known as cross-linking. This phrase "cross-linked" will be noted in the manufacturers' specification sheets and is usually associated with considerable increases in the physical strength of a material. Most polymers consist of molecular chains (long series of chemical groups joined end to end). These groups tend to align during processing like short lengths of chain piled in a box. The strength of the material is related to the length and strengths of these chains. Cross-linking, as the name implies, involves adding extra links between each chain and its neighbors. This process has gained importance and specification sheets should be studied for resulting changes in physical and molding conditions.

Physical properties and molding conditions of many commonly used materials are listed in Appendix III. This appendix is only a guide. Space prevents a complete, comprehensive list of materials. It is highly recommended to refer to the material manufacturer's information data sheet before processing any thermoplastic. Any person who works with plastic materials should be aware of any cautions, hazards, or special handling procedures that may be required.

CHAPTER FOUR

EPOXY TOOLING

No study of low-cost tooling should be considered complete without a long careful look at the advantages offered by poured epoxies. The cavity, and often the core of a mold, can be produced by pouring and then heat curing a high temperature epoxy around a pattern or prototype part. When the pattern is removed, every detail, even fingermarks on the pattern, will be faithfully reproduced.

ADVANTAGES

The advantages of epoxy tooling include the short time required to produce an extremely accurate and detailed mold, the low cost of materials and the very significant savings in toolmaking labor. After some practice, good molds can be made by persons unskilled in normal moldmaking procedures. The equipment used - a mixing bowl, stirring stick and simple oven - are far more readily available in the laboratory than the lathe, mill and hobbing press.

LIMITATIONS

The limitations of epoxy tooling are involved with the need for an accurate pattern or prototype part to duplicate, and the life of the tool in terms of its ability to produce duplicate parts. Epoxy materials, although hard and rigid to the touch, are not as strong as aluminum or kirksite. The mold wear from abrasion is greater. Epoxies are generally strong in compression but poor in tensile or shear load conditions. It is usually necessary to back-up the epoxy with a metal box and to avoid thin, unsupported members (wall sections or other details) within a cavity or core.

An additional limitation involves the rate at which epoxy can transmit and dissipate the heat created in the process of injection molding. Simple two part epoxies are, in fact, good insulators. To overcome this problem, epoxies used in preparation of molds are heavily filled with powdered metal, usually aluminum. These fillers improve heat transmission and increase the strength and surface hardness of the materials. It is also common to have long mold closed/injection cycles (often two to three times longer than those with conventional metals) due to the slow heat transfer rates.

TYPES

Mold making epoxies are of the two-part type. Part "A" is a metal-powder filled resin. Part "B", the hardener, is either a liquid or a powder. These are mixed thoroughly together usually in a ratio of three parts "A" to one part "B". Once mixed, the material has a workable life of about a half-hour before starting to gel. Three companies that make epoxy materials used to produce injection mold cores and cavities are The Devcon Corporation, Furane Products, and Ren Plastics (a division of Ciba-Geigy Corporation).

All of these materials require heat curing. Once cured, the epoxies will withstand injection molding of thermoplastic materials at 600°F or less.

ECONOMICS

The costs of epoxies used for moldmaking are in the range of $18 to $20 per pound. The volume of one pound is approximately 16 cubic inches of mixture. When using a metal back-up shoe around the cast resin, it is seldom necessary to use more than half an inch thickness of epoxy. This means that when making a core and cavity for a part 3" x 3", the total epoxy used would be approximately ½ pound or $10 maximum cost.

The shoes or back-up boxes can be reused. Once a mold has completed its required production life, the epoxy can be removed and the shoes are then available for housing a new mold (or re-pouring the old one should it be damaged or wear out).

Experience has shown that the economic savings involved with epoxy tooling housed in reusable shoes can be as great as 70% of the cost of conventional tooling. These costs do not include the availability of metal working equipment required for conventional tool building.

MANUFACTURING OF EPOXY MOLDS

Design

There are two basic types of epoxy tools used for injection molding. These are the simple short-life hand mold (see page 92), and the Class "B" short-run tool, cast directly in the A & B plates of a conventional mold base (see page 94).

A simple drawing should be prepared for the mold, indicating the size of the pocket and the position of the parting line. A good practice is to draw the outline of the pattern first using a red pencil. Then draw the mold around the pattern using the parting line and the sprue positions to locate the mold plates. Two views, a plan and a side view, will be necessary to show the details and establish the pocket size. A good rule of thumb is to allow one inch of aluminum or a half inch steel plate around the epoxy as a back-up.

Pattern Making

The pattern can be made of any material which will withstand the first stage processing temperatures of approximately 200°F without deforming or giving off gas. Metal, plastic and wood are most commonly used. Metal patterns should be free of bumps, machine marks, or rough surfaces. Plastic patterns should be of sufficient strength and temperature resistance to allow for removal from the solidified epoxy after the first heat stage of curing (pre-cure).

Wood patterns, which are easily constructed, are the most critical in terms of finishing requirements. All porosity must be eliminated and the wood grain smoothed, or the poured epoxy will adhere firmly to the pattern. It has been found from experience that the shellac-based varnishes, often used for wood pattern finishing in the foundry industry, are not suitable for use with epoxies. They tend to soften, become sticky, and often give off gas during pre-cure baking. The liquid polyethylene finishes and the vinyl emulsion wood glues, when brushed or rubbed well into the wood and thoroughly dried are more acceptable.

The final preparation of the pattern is a most important phase of epoxy moldmaking. First, rub or spray a hard wax-type parting agent on the pattern and allow this to dry. Then buff well and repeat the process. When you are absolutely sure that the pattern has been thoroughly coated with parting agent, wax it once more! Remember, epoxies are among the best known adhesives and will bond readily to most surfaces. They will not bond to a surface which is well waxed or well protected with silicone. Use one or both of these parting agents generously.

For critical dimensional areas, the pattern should be made larger than the required finished product by the amount dictated by the "shrink" of the thermoplastic material to be injected into the finished mold. If a part dimension must be one inch long when molded in ABS with a shrink rate of .005 inch per inch, then the pattern must be made 1.005 inches long. The shrinkage of the epoxy moldmaking material is very low. In sections of no more than a half-inch thick, it can be disregarded entirely.

Mounting the Pattern

Before the epoxy can be poured, the pattern must be properly mounted. When it has a flat surface at the parting line, such as a flat disc or cup-shaped item, the pattern can be easily secured to a flat surface such as a sheet of glass or metal using a layer of double-backed tape. The entire surface must now be waxed and buffed and can be lightly sprayed with silicone parting agent. Position over this the shoe or box and secure in place with weights or clamps.

When a part has detail on both sides of the parting line (e.g. sphere or a cylinder), it must be mounted into a layer of soft clay with the lower portion submerged into the clay so that the other surface of the clay is at the parting line (imagine a marble pressed into a layer of clay until half submerged). The top surface of the clay should then be leveled and smoothed. Next, oven-dry the clay with the pattern in place. Plaster of paris may be used in place of clay and should be also thoroughly dried.

Next, thoroughly seal and wax the clay or plaster as described for wood preparation. Finally position the box or shoe over the pattern and secure in place.

The complete assembly should then be put on a heater plate or preferably in an oven and raised gently to 200°F.

Mixing the Epoxy

It is essential for the preparation of good epoxy mixes that two rules be strictly observed. First estimate the amount of epoxy required using the known fact that one pound equals 16 cubic inches. Then MEASURE CAREFULLY the CORRECT amount of hardener, stirring well with a tool. The mixture must now be THOROUGHLY MIXED by stirring slowly by hand for at least five minutes. Then return the mix to the oven.

Machine mixing is not advisable because it folds air into the mix, and air entrapment is the biggest cause of epoxy mold failure. Bubbles on or near the mold surface will rupture under molding pressure and cause parts to hang in the mold.

While the mix is reheating and bubbles are riding to the top, the heated mold half can be removed from the oven and positioned for pouring. Remember that as epoxy is poured into the molding box, air must be allowed to escape. It is good practice to put the mold and plate assembly on a heater plate and tilt it slightly so that the epoxy can be poured at the low end of the mold. The level of the liquid epoxy thus rises slowly in the mold avoiding air entrapment. When full, the mold can be returned to the oven for curing. If possible, leave the filled mold in the oven at 200°F overnight.

When fully cured, remove the flat plate from the parting line of the mold. Leave the pattern in the mold or replace it into the molded cavity. Once again, thoroughly wax, buff, rewax and spray the mold parting line and underside of the pattern. Place the lower mold shoe in position using the dowels to locate it accurately. Bolt or clamp the mold halves together.

Mix, heat and pour in the lower mold shoe as per the upper half of the mold and pre-cure in the oven. Next remove the pattern and complete the mold cure as recommended in the epoxy manufacturer's instructions.

Mold Finishing

In many cases, the only machining required to complete the mold is the drilling and the hand reaming of the sprue passage. As for all metal molds, the sprue must be tapered. Wherever possible, use a straight flute tapered pin reamer.

Runners should be cut where necessary using a ball end mill cutter. There should be no need to polish an epoxy mold if the pattern was correctly finished; however in areas where the epoxy is machined a good polish can be obtained with the use of a lightly abrasive metal polish applied with a soft wood polishing stick or a cotton-tipped swab. After polishing, apply a coating of hard wax and buff well.

If an abrasive plastic material such as a "glass filled" is to be injected into the mold, it is possible to Teflon® coat the core and cavity. First remove all traces of wax from the epoxy using a solvent or a degreaser such as carbon tetrachloride; then spray or paint on a thin coating of Teflon "S" and air dry. Next bake the mold at 350°F for two hours to harden the Teflon.

(Note: Teflon is a registered tradename of the DuPont Company. Teflon is a PTFE compound. PTFE stands for polytetrafluoroethylene which is a class of fluoroplastic. PTFE is sold under other tradenames such as Halon by Ausimont, USA, Fluon by AGCE Chemicals, and Hostaflon by Dyneon LLC.)

Metal core pins or inserts should be added to the mold after the final oven cure. DO NOT mold metal inserts, cores, or ejector pins into the epoxy. These will all complicate the moldmaking and tend to cause stresses and air entrapment. Add these details as is done with conventional all-metal tooling.

The remaining item is venting, which is extremely important in epoxy tooling particularly since injection pressures should be kept as low as possible. Venting techniques described in the metal tooling chapter apply equally to epoxy tooling. Finally, it is recommended that a good mold release agent be sprayed into the mold cavity and core. This is preferable to a layer of well buffed hard wax.

RUNNING OF EPOXY MOLDS

In order to prepare and extend the life of epoxy tooling, care should be taken during its use to prevent accidental damage. First, gently warm the mold to its running temperature as required to suit the material to be injected. Clamp the mold firmly but slowly (without sudden impact). Inject the material at a moderate or slow rate without undue use of high pressures.

Because of slower-than-metal heat transfer rates, the chill times after the completion of injection and before mold opening should be extended by approximately a factor of two. A part which in metal tooling would chill in 15 seconds should be allowed a full 30 seconds to chill (possibly longer). Adjust this "holding time", including maintaining the pressure of the injection ram, until acceptable parts and cycles are attained. If the temperature of the mold continues to rise, reduce the frequency of injecting parts into it. After a part is ejected, wait a short time before reusing the mold. Class B tools can also be cooled by circulating cold water through holes drilled in the shoes or mold plates surrounding the epoxy.

MOLD LIFE

The complexity of the part being shot, the care taken in moldmaking, handling and use, and the type of material being processed all affect the life of an epoxy tool. One hundred parts is a normal expected life of a tool maintaining close tolerances and using high temperature materials.

Some epoxy molds can produce at least a thousand parts if carefully used with non-abrasive plastic materials. There are instances on record of epoxy tools producing over 50,000 shots. If the pattern is retained after completing the mold, a worn or damaged mold can be remade using the shoes or mold plates a second or third time. Often only one side of a mold need be rebuilt. Simply place the pattern into the good half of the mold and recast the worn section.

In summary, epoxy tooling has been found to be an excellent prototype alternate technique - particularly when dealing with complex shaped parts. In the absence of significant machine shop capability, it may be the best economical technique for producing useful and quality prototype parts. In some cases, it is the mold building technique of choice for making low volume production runs. Epoxy tooling is a significant viable avenue in the search for practical prototype and low production methods.

CHAPTER FIVE

CASE EXAMPLES OF SHORT-RUN MOLDING REQUIREMENTS

The following case examples are intended to illustrate tool design, construction, material selection and the molding process. In most examples, short-run molding is compared with an alternative method of fabrication and costs of both approaches are estimated. These examples are based on actual case histories: however, where necessary, costs and lead times have been approximated. Also adjustment of hourly rates for inflation and local conditions may be required in some examples especially as the cost justifications have not been "rescaled" since their actual occurrence. As an average, the estimated cost savings at any point in time are in excess of 65 percent of the alternate method of fabrication, and the savings in lead times are equally significant. You will note that for many of these examples, the only possible manufacturing process was injection molding.

The selection has been grouped as follows:

A Series	-	2 plate tools emphasizing lathe work
B Series	-	3 & 4 plate tools emphasizing lathe work
C Series	-	2 plate tools emphasizing mill work
D Series	-	multi-cavity & semi-automatic tools
EP Series	-	epoxy tooling
EDM Series	-	tools using EDM technique

Emphasis has been placed on hand molds and semi automatic tools of the Class B designation. Some repetitive items such as mold mounting holes and slots, hidden lines and other common details have been deleted from some sketches in order to "highlight" other mold design features. Many of these could have been built as Class C tools, the parts finished with secondary operations, and the total economics of the job improved.

The indirect advantages of this short-run injection molding approach include: reduction of parts inventory as interim production requirements for parts can be completed and the tool returned to storage; flexibility of production scheduling due to low lead times for first samples and quick set-up for subsequent production runs; savings of purchasing and accounting overheads; and full control by production management over quality assurance.

If your applications are primarily in R&D and product development, the in-house injection molding approach enables you to maintain better control over proprietary information, promotes strong feedback between design and molding results, as well as rapid project turnaround at lower tooling costs.

MOLD MAT'L: 3" OD. C.R.S. 1015 OR ALUM 2024-T4		
COVER-INDICATOR LIGHT.	MAT'L COLORED POLYPROPYLENE	DRAWING NUMBER A-1

PART REQUIREMENT

DESCRIPTION: Cover/Indicator — NUMBER: A-1

MATERIAL: Translucent - color tinted plastic

QUANTITY: 1,000 parts

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Purchased item, lead time 6 weeks	
3 colors - varying color ratios	
Minimum purchase - 1,000 parts x 55¢ each	$550

SHORT RUN MOLDING METHOD:

Tool cost - 4 hours x $10/hr. + material	$ 55
Molding cost - 12 hours x $5/hr. + material	65
Lead time - 1 week	$120
Estimated savings: 5 weeks and	$430

ENGINEERING DETAIL

MATERIAL SELECTION: "Cellulose" acetate, butyrate or propionate

Reason: Optically good, translucent colors available, high-impact strength, flexible (for press fit to panel), dimensionally stable

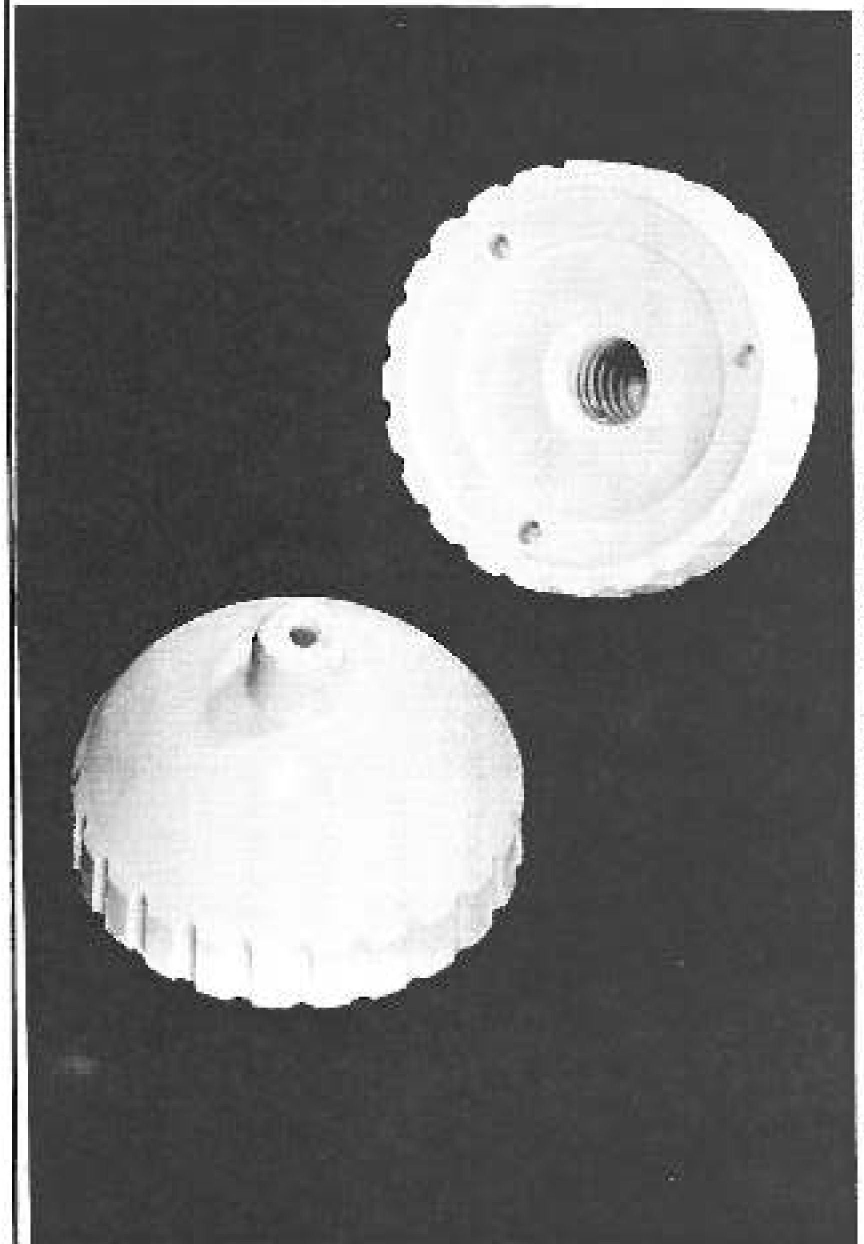
TOOL: "A" plate part cavity with small sprue gate for aesthetic reasons

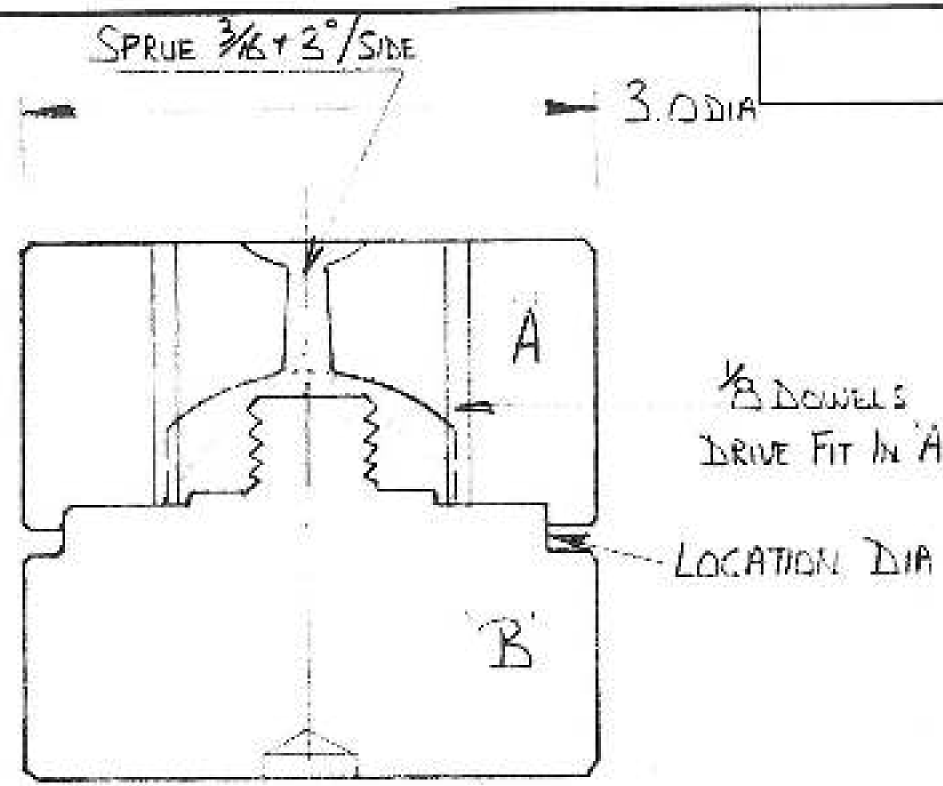
"B" plate polished and sandblasted to give diffused light effect

EXPECTED TOOL LIFE: 5,000 parts

PRODUCTION RATE: 80 parts per hour - by hand

EQUIPMENT: Morgan-Press G-55 with "B" (3/16") orifice ball nose nozzle and nozzle adapter





(a) SHOOT W/ 'B' SIZE BALL NOZZLE

CAP NUT MAT'L NORYL + 20% GLASS | DRAWING NUMBER A-2

PART REQUIREMENT

DESCRIPTION: Cap Nut — NUMBER: A-2

MATERIAL: Glass-filled Phenylene Oxide (Noryl*)

QUANTITY: 100 parts

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Machined from acetal (Delrin**) bar stock	
Cost to lathe and mill - 30 hours x $10/hr	$300

SHORT RUN MOLDING METHOD:

Tool cost - 6 hours x $10/hr + material	$ 65
Molding cost - 2 hours x $5/hr + material	12
Lead time - 2 days	$ 77
Estimated savings:	$223

ENGINEERING DETAIL

MATERIAL SELECTION: 20% Glass-filled Phenylene Oxide

Reason: High strength, low cold flow, light weight

TOOL "A" plate is cavity and sprue gate

"B" plate is core and base

EXPECTED TOOL LIFE: 500 parts

PRODUCTION RATE: 60 parts/hour - hand operation

EQUIPMENT: Morgan-Press G-55 with heater plate and "B" (3/16") orifice ball nozzle

*Noryl is a trade name of the General Electric Co.

**Delrin is a trade name of the DuPont Co.

TIMER KNOB W/SET SCREW HOLE MAT'L 'NORYL'		DRAWING NUMBER A-3

PART REQUIREMENT

DESCRIPTION: Timer Knob with set screw — NUMBER: A-3

MATERIAL: Noryl

QUANTITY: 200 parts

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Turn and mill from aluminum bar - anodize black	
Cost - 200 x $3.75 each	S750

SHORT RUN MOLDING METHOD:

Tool cost - 12 hours x $10/hr + material	$135
Molding cost - 7 hours x $5/hr + material	40
Lead time - 3 days	$175
Estimated savings: 2 weeks and	$575

ENGINEERING DETAIL

MATERIAL SELECTION: Noryl, SE-100, black

Reason: High strength, low cold flow, high heat resistance, good surface finish

TOOL: "A" plate is core and reverse tapered sprue with gate.

"B" plate is base and locator for insert.

Insert is hobbed after lathe turning and pieces fit into "B" plate.

Screw is standard allen cap.

EXPECTED TOOL LIFE: 500 pieces

PRODUCTION RATE: 30 parts/hour - hand cycle

EQUIPMENT: Morgan-Press G-55 with heater plate, "B" ball nozzle and nozzle adapter

KNOB - CONTROL VALVE MAT'L P. PROP.		DRAWING NUMBER A - 4

PART REQUIREMENT

DESCRIPTION: Knob, Control Valve (Custom) NUMBER: A-4

MATERIAL: Polypropylene - black

QUANTITY: 50 pieces

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Purchase a standard knob and modify to fit square shaft	
Cost - 50 x $5 (Estimated)	
Lead time - 3 weeks	$250

SHORT RUN MOLDING METHOD:

Tool cost - 10 hours x $10/hr + material	$125
Molding cost - 2 hours x $5/hr + material	12
Lead time - 3 days	$137
Estimated savings: 2 weeks and	$113

ENGINEERING DETAIL

MATERIAL SELECTION: Polypropylene - black

Reason: High-lustre finish, will press onto shaft without cracking, low cost and easy to mold

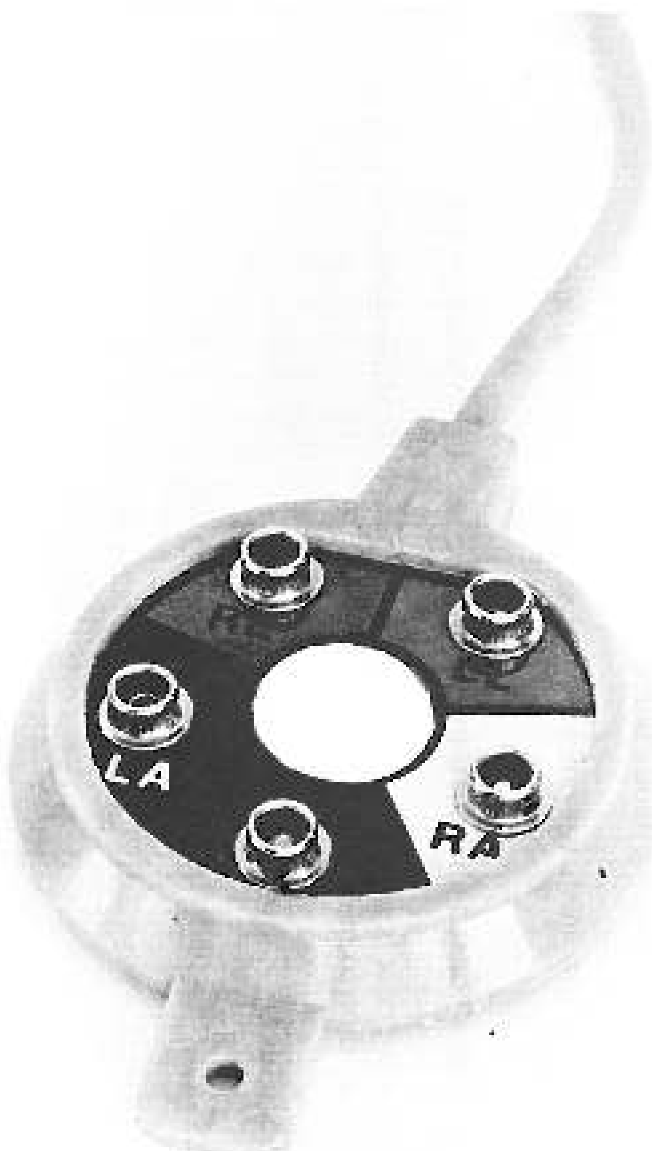
TOOL: "A" plate - cast aluminum with standard purchased knob as pattern

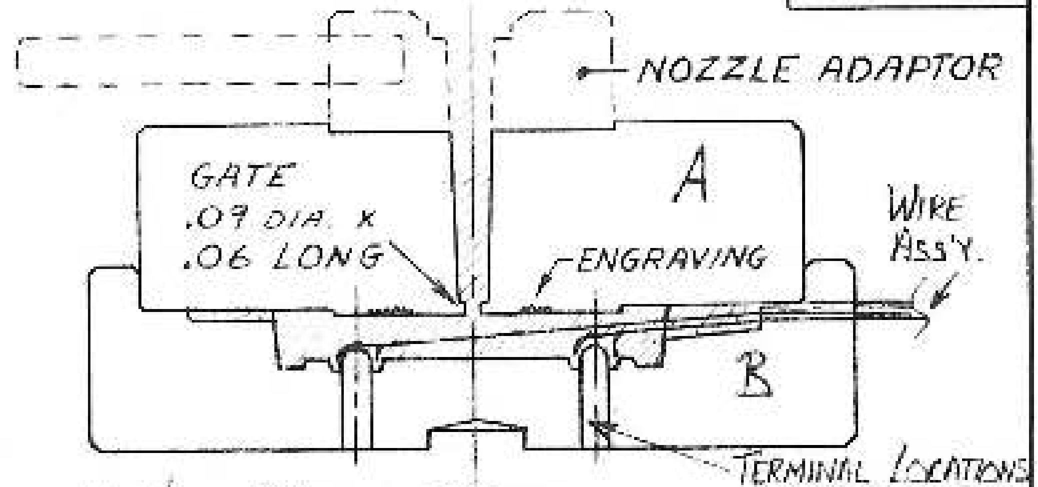
Casting cost is about $15 in #356 alloy. Core is ¼" diameter dowel with flats ground on to match shaft of valve.

EXPECTED TOOL LIFE: 500 pieces

PRODUCTION RATE: 40 parts/hour - hand cycle

EQUIPMENT: Morgan-Press G-55T with "B" ball nozzle and nozzle adapter





(a) LOAD WIRES & TERMINALS.

(b) SHOOT THRU ADAPTOR W SHUT-OFF NOZZLE.

PHOTO ELECTRIC SWITCH COVER MAT'L A.B.S		DRAWING NUMBER B-5

PART REQUIREMENT

DESCRIPTION: Cover - Photo Electric Switch   NUMBER: B-5

MATERIAL: A.B.S.

QUANTITY: 25 prototype parts and sales samples for customer approval and evaluation of ultrasonic welding

---

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Bypass prototyping stage - go directly to production	
Tooling delays sales samples	
Lead time- 16 weeks	
Costs - Multi-cavity steel mold	$7,400
High probability of design change following initial production	

SHORT RUN MOLDING METHOD:

Tool cost - 12 hours x $10/hr + material	$ 130
Molding cost - 2 hrs x $5/hr + material	12
Total cost, samples - engineering, sales customers	$ 142
Lead time - 3 days	

NOTE: Prototypes were granted provisional UL approval. Estimated savings: 15 weeks of time, value of design evaluation before high tooling dollar investment, opportunity to test molding of lens into part and ultrasonic welding parameters

---

ENGINEERING DETAIL

MATERIAL SELECTION: A.B.S.

Reason: Parts to be ultrasonically welded on assembly. Outdoor usage requires parts to be ultraviolet resistant and weatherproof with good electrical resistance and low cost.

TOOL: "A" plate is core and sprue gate.

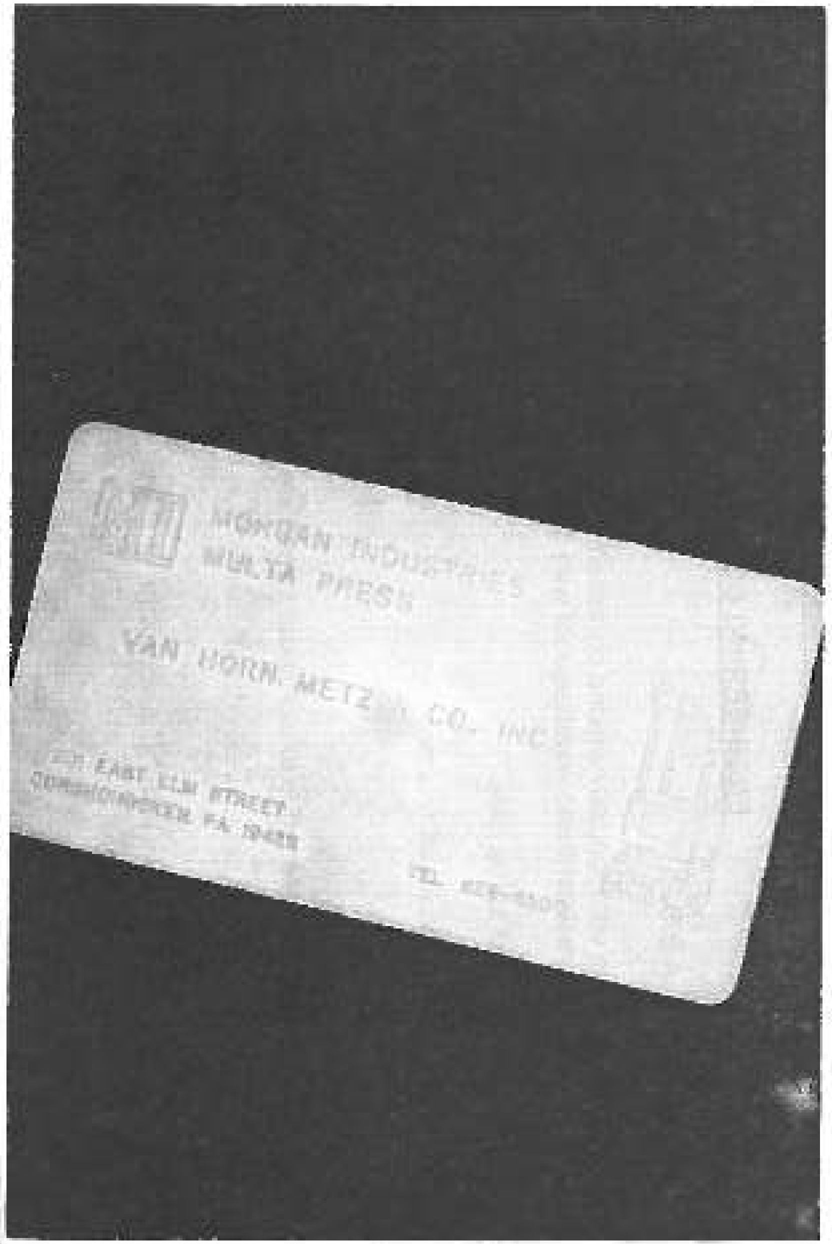
"B" plate is cavity and insert retainer.

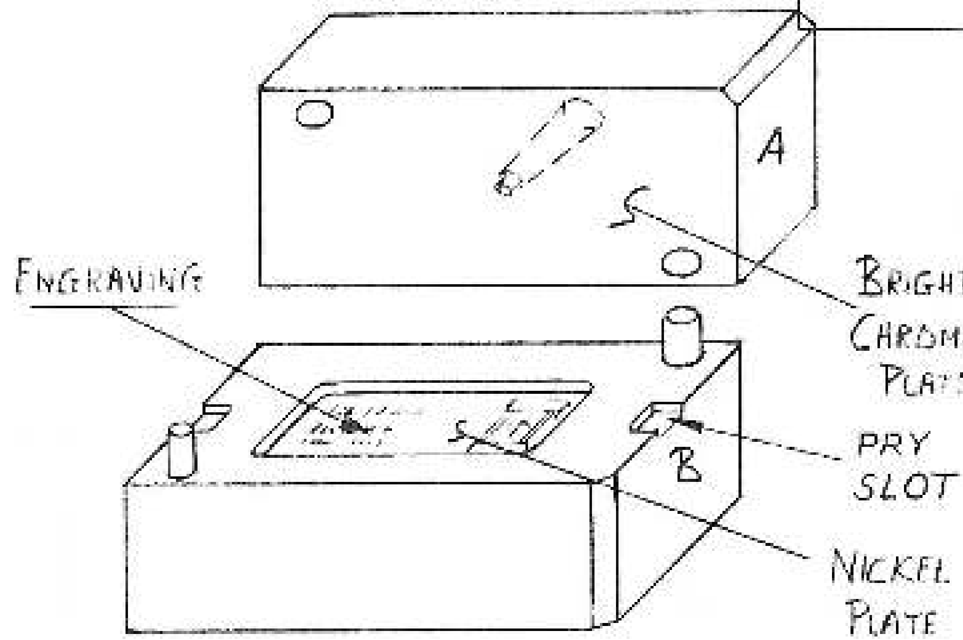
Base is reverse core.

EXPECTED TOOL LIFE: 100 pieces, due to aluminum thread wear

PRODUCTION RATE: 12 parts/hour

EQUIPMENT: Morgan-Press G-100T with "B" ball nozzle





(a) SHOOT THRU NOZZLE ADAPTOR
(b) OPEN MOLD - STRIP PART FROM 'B'
(c) ROTATE ADAPTOR TO BREAK GATE
(d) TRIM CARD.

MOLD MAT'L ALUM 2024-T4 - 1½ PLATE		
BUSINESS CARD -	MAT'L STYRENE-COLORS	DRAWING NUMBER C-1

DIETZGEN NO. 169MP AUSPROOF "MASTER FORM"

PART REQUIREMENT

DESCRIPTION: Engraved Chip/Business Card NUMBER: C-1

MATERIAL: Any conventional thermoplastic - any color

QUANTITY: Estimated 5,000 pieces

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

This is a demonstrator tool for customer education and evaluation of materials and color mixes. No previous method existed. Tool used to demonstrate machine "in plant" by distributors.

SHORT RUN MOLDING METHOD:

Tool cost - Milling 6 hours x $10/hr + material	$ 65
Engraving - $40 (Outside Vendor)	40
Chrome and Nickel Plating (Outside Vendor)	30
	$135

ENGINEERING DETAIL

MATERIAL SELECTION:

Mold designed and gated to run any conventional material (pre-colored or dry-colored)

TOOL: Aluminum 2024-T4

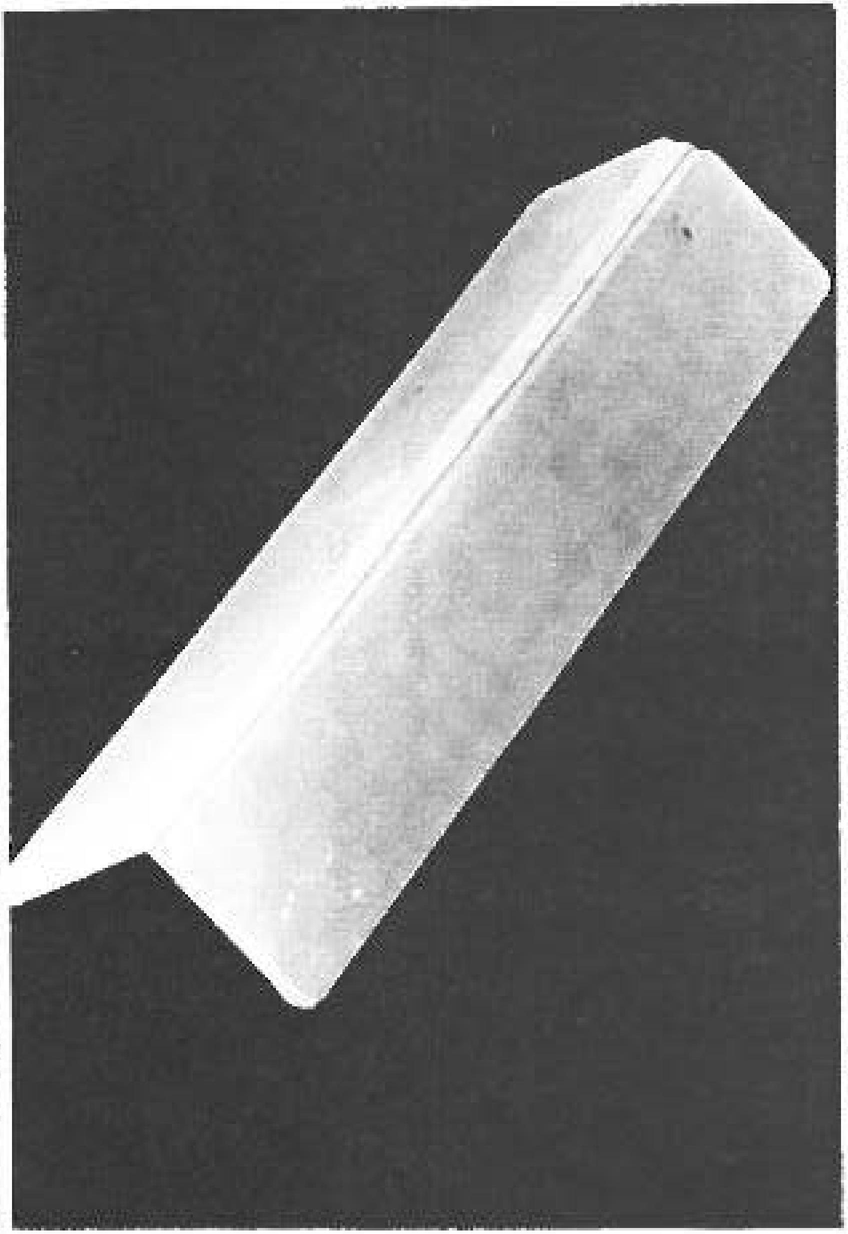
Chrome-plated and polished "A" plate for high gloss finish for color evaluation

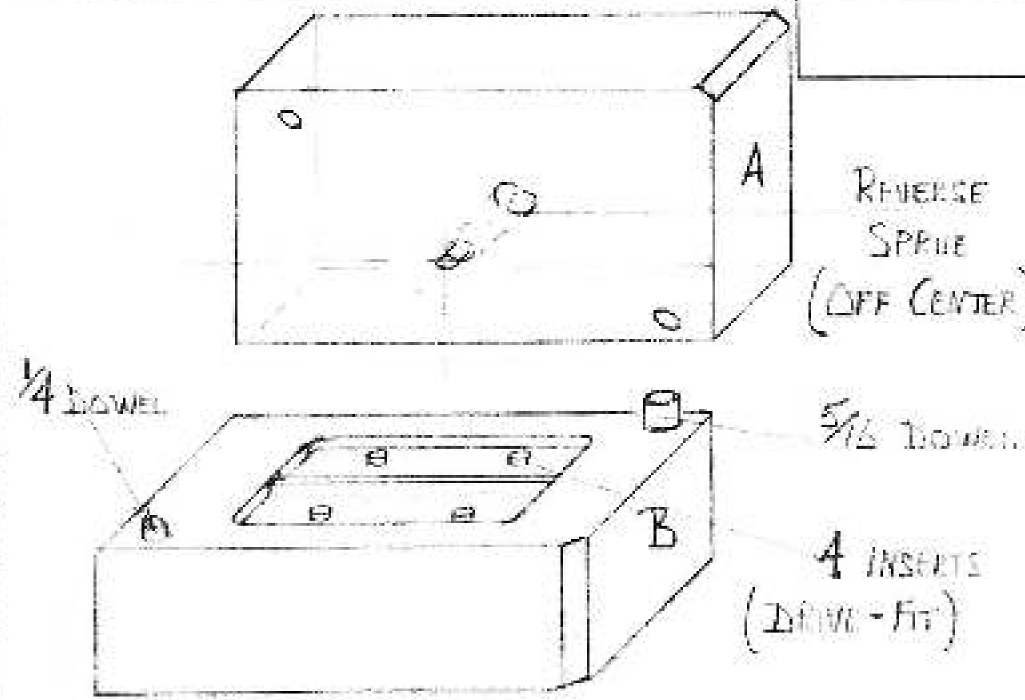
Cavity nickel plated for improved surface finish and contrast

EXPECTED TOOL LIFE: 5,000 parts

PRODUCTION RATE: 60 pieces/hour depending on material

EQUIPMENT: Any Morgan-Press model with ball nozzle and nozzle adapter





(1) SHOOT 'THRU' NOZZLE ADAPTOR
(2) OPEN MOLD & STRIP PART FROM 'B'
(3) ROTATE ADAPTOR TO BREAK GATE
(4) FLEX HINGE - BOTH WAYS - WHILE STILL HOT

2 PLATE MOLD . MILLED CAVITY . W DOWEL INSERTS		
SCALE: 1.50'	APPROVED BY	DRAWN BY PM
DATE.		
MOLD MAT'L ALUM 2024-T4 - 1/2" PLATE		
LIVING HINGE	MAT'L POLY ALLOMER	DRAWING NUMBER C-2

PART REQUIREMENT

DESCRIPTION: Living Hinge NUMBER: C-2

MATERIAL: Polyallomer, carbon black filler (in different concentrations)

QUANTITY: 25 pieces, for sub-zero temperature hinge evaluation

---

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Part must be injected molded	
Estimated tooling cost	$480
Set up and running - five color mixes	120
Lead time - 6 weeks	$600

SHORT RUN MOLDING METHOD:

Tool cost - milling of blocks and cavity (12 hours x $10/hr) + material	$140
Molding cost - 5 batch mixes and purging (5 hours x $5/hr) + material	30
Lead time - 3 days	$170
Estimated savings: 5 weeks and	$430

ENGINEERING DETAIL

MATERIAL SELECTION: Polyallomer

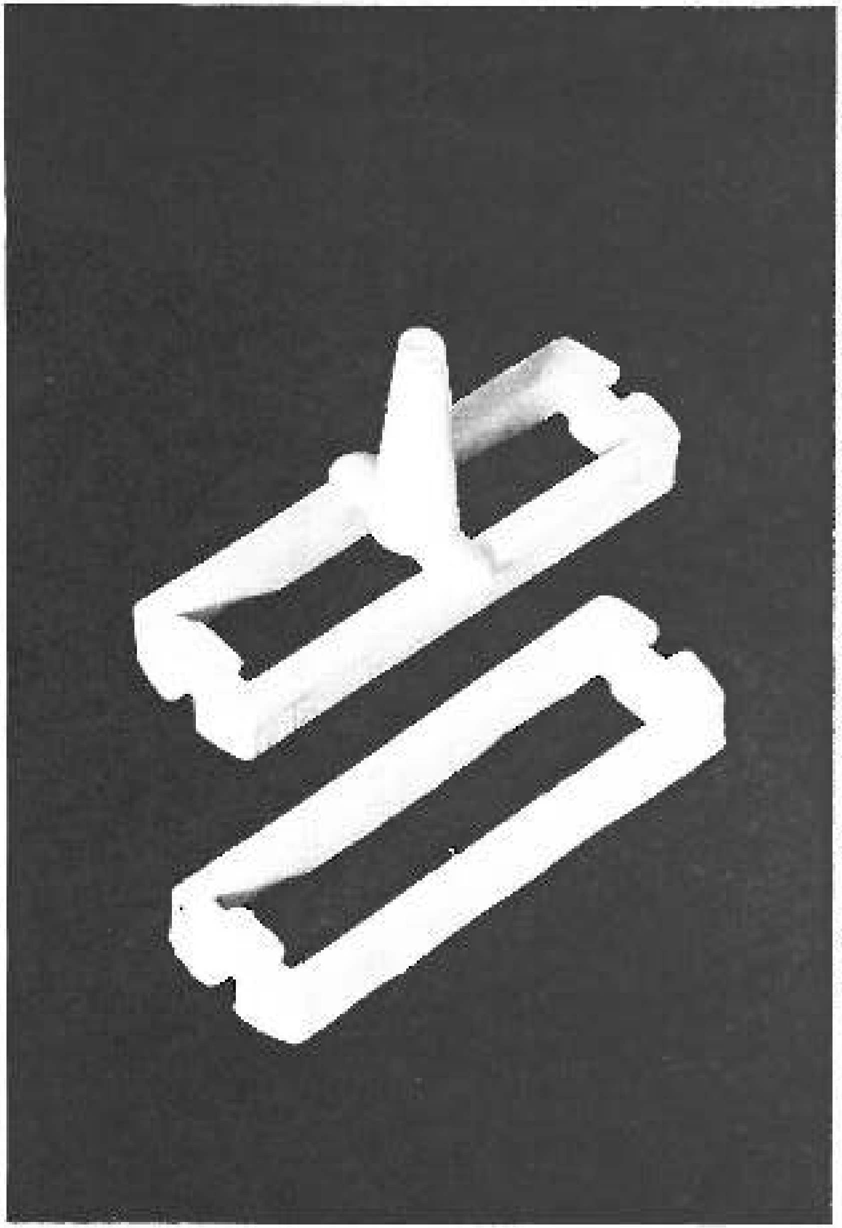
Reason: A good hinge material, flows easily through small section, good low temperature physical characteristics

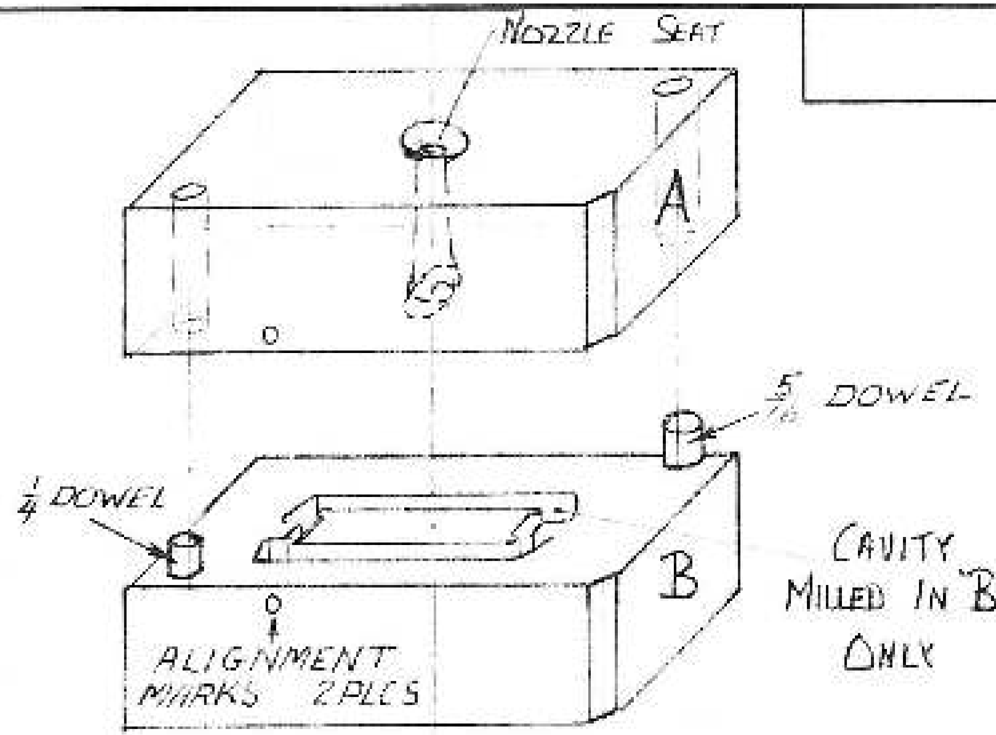
TOOL: Aluminum 2024-T4, steel core pins (dowels)

EXPECTED TOOL LIFE: 500 pieces

PRODUCTION RATE: 5 parts/hour due to filler mixing and changeover

EQUIPMENT: Morgan-Press G-55T with ball shut-off nozzle and nozzle adapter





(a) SHOOT W BALL-SHUT-OFF NOZZLE
(b) OPEN MOLD - PART STAYS IN 'B'
(c) PULL PART USING SPRUE
(d) TRIM PART

2 PLATE MOLD - MILLED CAVITY		
SCALE: 1.50	APPROVED BY	DRAWN BY GP

MOLD MAT'L 2024-T4		
SPRING - LATCH RETAINER MAT'L DELRIN.		DRAWING NUMBER C-3

PART REQUIREMENT

DESCRIPTION: Spring NUMBER: C-3

MATERIAL: Delrin 500, natural color

QUANTITY: 200 pieces

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Alternate method, machine from Delrin plate	
Estimated mfg. cost (due to tight tolerances)	$800
Lead time - 2 to 3 weeks	

SHORT RUN MOLDING METHOD:

Tool cost - milling of cavity & block (8 hours x $10/hr) + material	$ 90
Molding cost - 4 hours x $5/hr + material	25
Lead time - 2 days	$115
Estimated savings: 2 weeks and	$685

ENGINEERING DETAIL

MATERIAL SELECTION: Delrin 500 natural

Reason: Excellent spring material, molds easily into hot mold

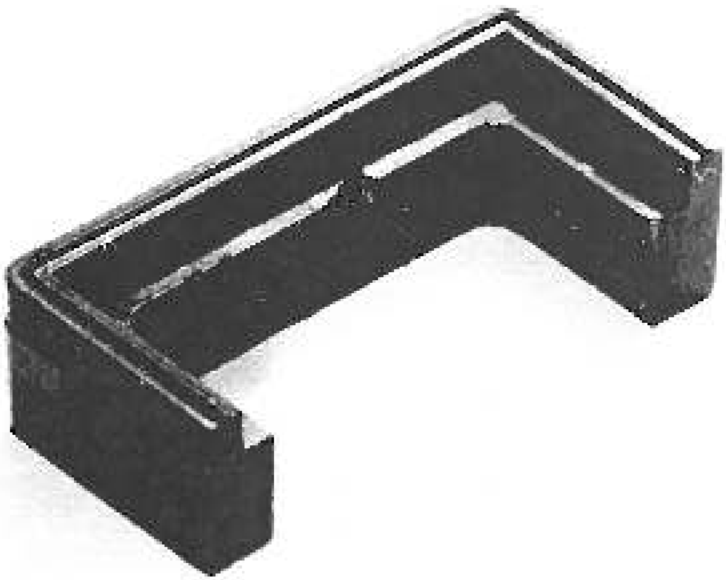
TOOL: Aluminum 2024-T4, 1" plate

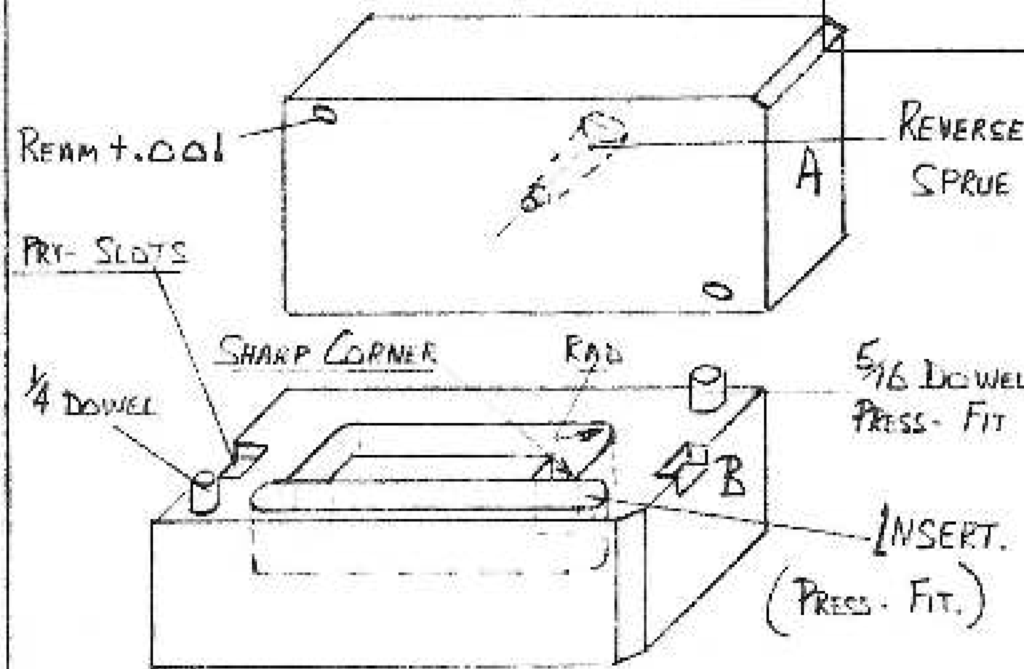
Mill cavity into "B" plate - no loose cores

EXPECTED TOOL LIFE: 500 pieces

PRODUCTION RATE: 60 parts/hour

EQUIPMENT: Morgan-Press G-55 with ball shut-off nozzle, nozzle adapter, and mold heater plate





(a) SHOOT W' NOZZLE ADAPTOR.
(b) OPEN MOLD - STRIP PART FROM B -.
(c) ROTATE ADAPTOR TO BREAK GATE.
(d) TRIM PART

2 PLATE + INSERT

MOLD & INSERT 2024-T4 - STEEL DOWELS		
BEZEL - WINDOW MAT'L A.B.S		DRAWING NUMBER C-4

PART REQUIREMENT

DESCRIPTION: Bezel NUMBER: C-4

MATERIAL: A.B.S. - black

QUANTITY: 200 (100 sets - 2 pieces to a set)

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Part must be injection molded - has a .008" high bead on after-surface for ultrasonic welding to mating assembly.	
Estimated cost of conventional tooling and parts.	$550
Lead time - 6 weeks	

SHORT RUN MOLDING METHOD:

Tool cost - mill cavity and insert (15 hours x $10/hr) + material	$160
Molding cost - 4 hours x $5/hr + material	25
Lead time - 1 week	$185
Estimated savings: 5 weeks and	$365

ENGINEERING DETAIL

MATERIAL SELECTION: A.B.S.

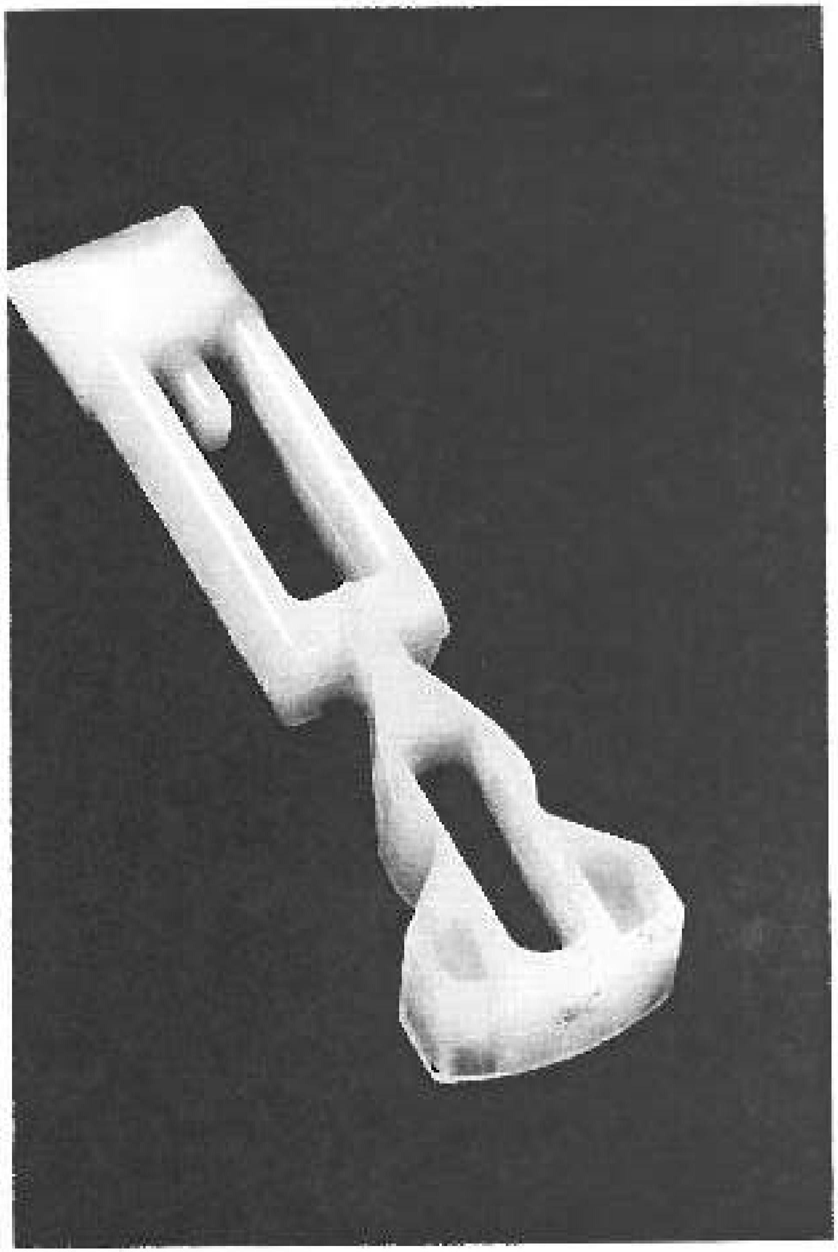
Reason: Has good appearance, good weldability and high strength

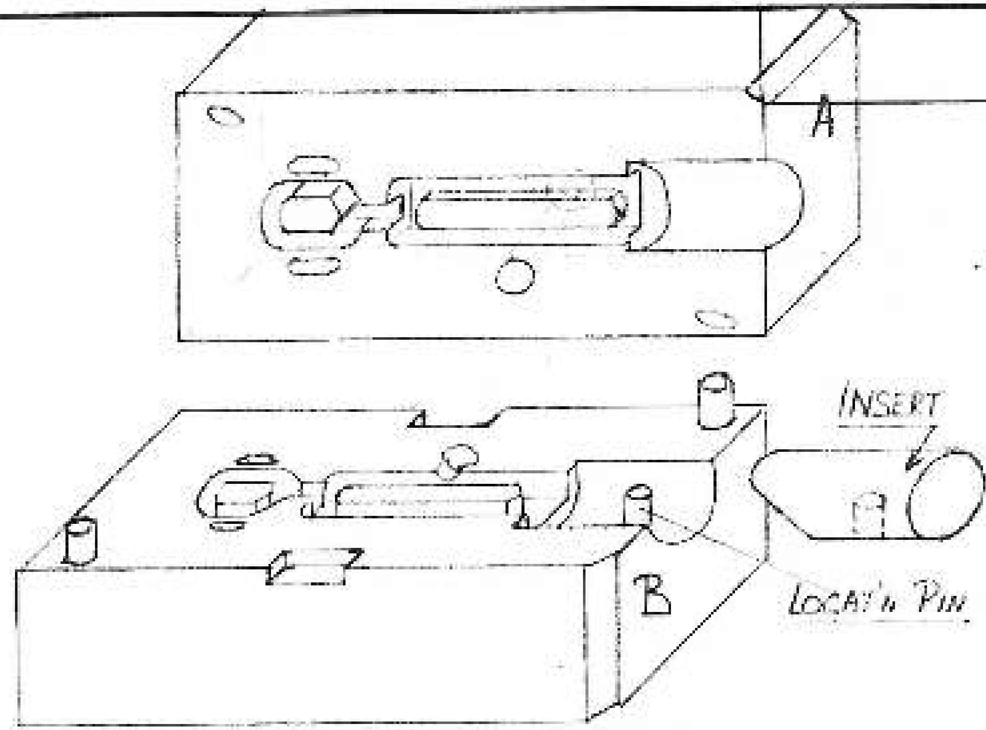
TOOL: Aluminum 2024-T4 - insert same

EXPECTED TOOL LIFE: 1,000 pieces

PRODUCTION RATE: 50/hour

EQUIPMENT: Morgan-Press G-55 with ball nozzle, nozzle adapter, pre-heat plate





(a) SHOOT W/ BALL SHUT-OFF NOZZLE
(b) OPEN MOLD - PART STAYS IN B.
(c) REMOVE INSERT
(d) USE SPRUE TO STRIP PART FROM 'B'

MOLD MATERIAL - ALUM-2024 - DOWELS STEEL		
LATCH SLIDER - MAT'L NYLON		DRAWING NUMBER C-5

PART REQUIREMENT

DESCRIPTION: Latch — NUMBER: C-5

MATERIAL: Nylon, bronze powder filled

QUANTITY: 100 parts - sales samples

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Parts must be molded	
Material not available in bar form	
Estimated cost of conventional tooling	$800
Set up and running	35
Lead time - 6 weeks	$835

SHORT RUN MOLDING METHOD:

Tool cost - milling, lathe turning (36 hours x $10/hr) + material	$380
Molding cost - 2 hours x $5/hr + material	15
	$395
Estimated savings: 5 weeks and	$440

ENGINEERING DETAIL

MATERIAL SELECTION: Nylon, bronze filled

Reason: High impact strength, low friction, looks like conventional bronze sintered part

TOOL: Aluminum 2024-T4

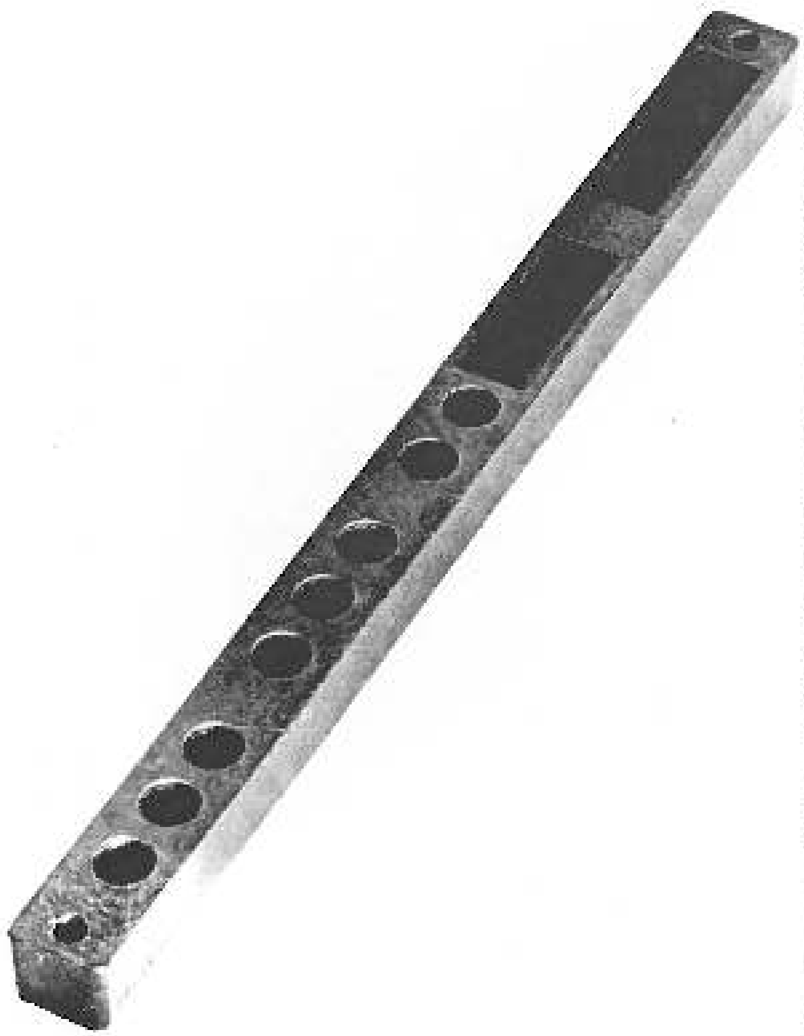
Cavity cut in A & B plates

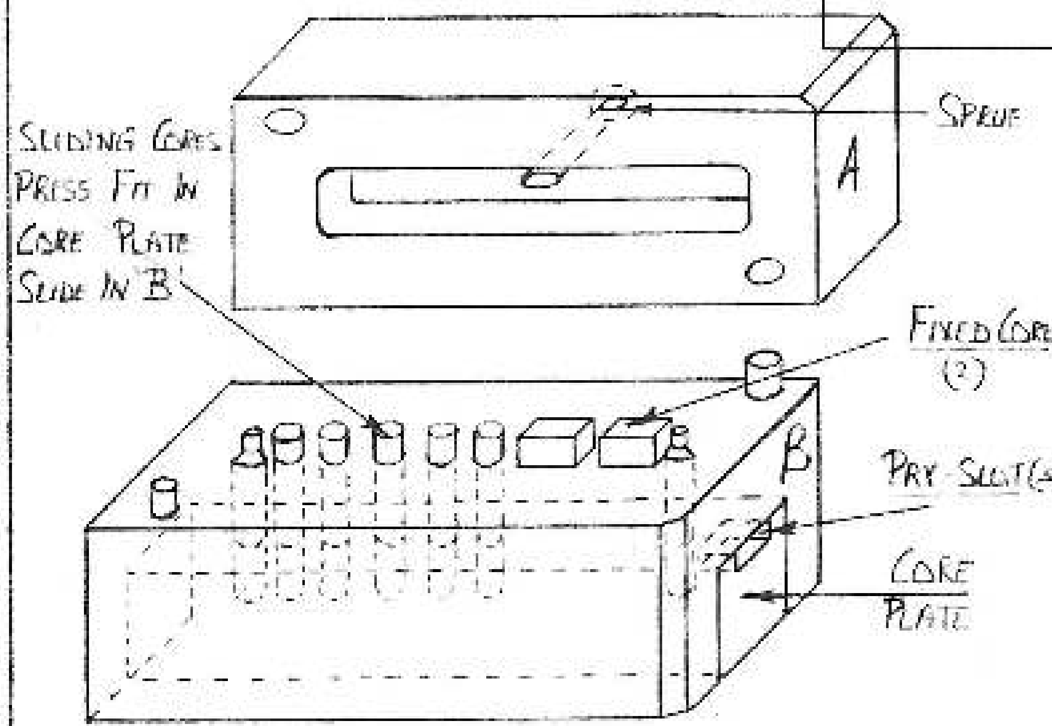
Off-set sprue, side gate

EXPECTED TOOL LIFE: 1,000 pieces

PRODUCTION RATE: 50/hour - hand cycle

EQUIPMENT: Morgan-Press G-100T with ball nose shut-off nozzle, nozzle adapter, and mold heater plate





(a) SHOOT W/ BALL NOZZLE - PULL SIDE CORES
(b) OPEN MOLD - PART STAYS ON CORES @ 'B'
(c) PRY-DOWN CORE PLATE TO CLEAR PART
(d) USE SPRUE TO STRIP PART FROM FIXED CORES
(e) TRIM PART.

5 PIN 'FEMALE' PLUG MAT'L VINYL		DRAWING NUMBER C-7

PART REQUIREMENT

DESCRIPTION: Three-pin Female Plug NUMBER: C-7

MATERIAL: Vinyl

QUANTITY: 10,000 assemblies

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Parts molded on production equipment in 5,000 part runs	
Tool cost	$1,600
Part price - 20¢ each	$2,000
Lead time - 8 weeks	$3,600

SHORT RUN MOLDING METHOD:

Tool cost - 30 hours x $10/hr + engraving + material	$ 380
Molding cost - 250 hours x $5/hr + material	1,330
Lead time - first part 2 weeks	$1,710
Estimated savings: 4-6 weeks and	$1,890

ENGINEERING DETAIL

MATERIAL SELECTION: Vinyl, soft grey

Reason: Matches wire coating in hardness and color

TOOL: Aluminum 2024-T4

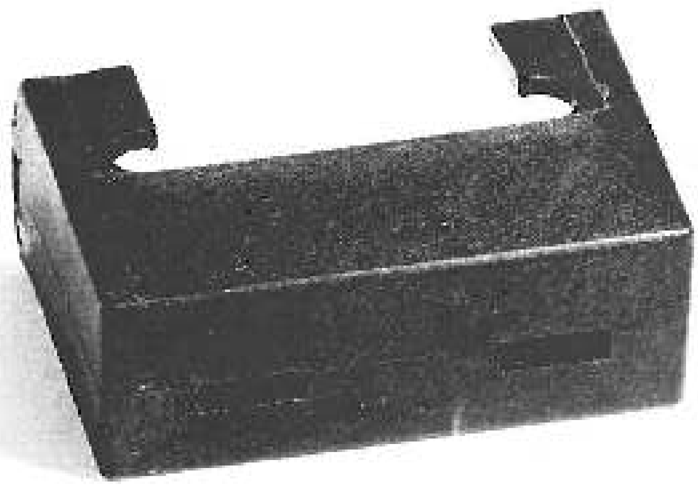
Not affected by corrosive nature of vinyl materials

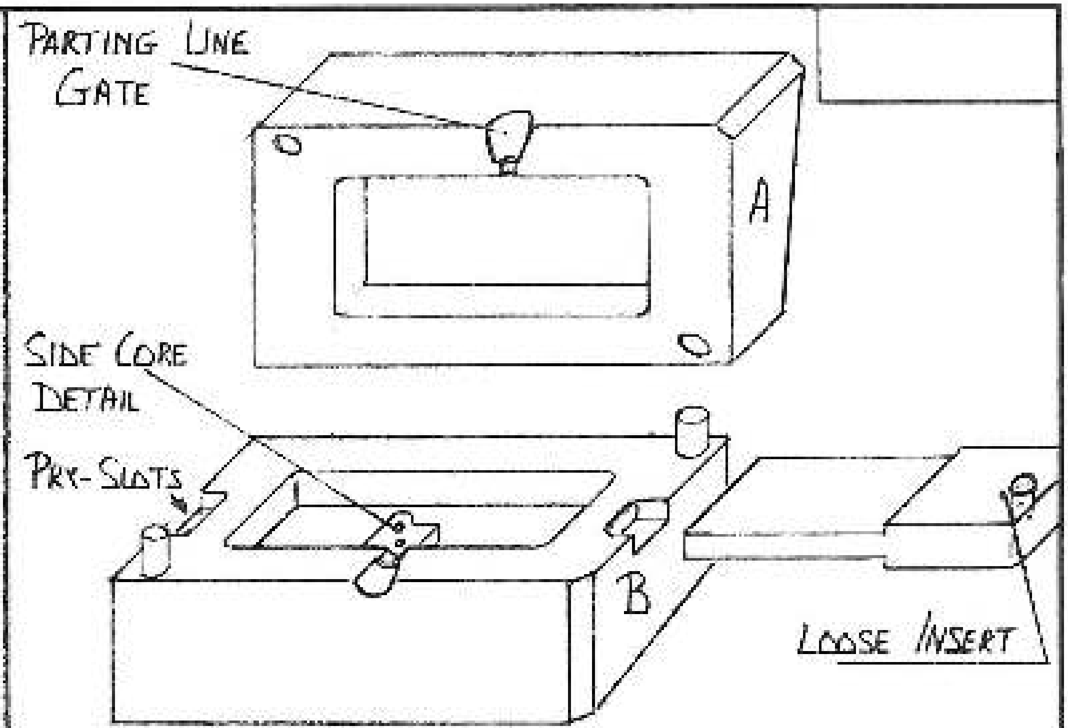
Must hard anodize aluminum or nickel plate steel

EXPECTED TOOL LIFE: 10,000 parts

PRODUCTION RATE: 40 parts/hour hand load wires to insert

EQUIPMENT: Morgan-Press G-55 with wedge block and flat nose shut-off nozzle





(a) LOAD INSERT INTO 'B' CAVITY
(b) PUT MOLD INTO WEDGE BLOCK - SHOOT W/ FLAT NOZ

ASTM TEST SPECIMENS		DRAWING NUMBER EDM-2

PART REQUIREMENT

DESCRIPTION: Tensile and Impact Test Specimens — NUMBER: EDM-2

MATERIAL: Any conventional thermoplastic

QUANTITY: Varies depending on data requirements

COST ANALYSIS

ORIGINAL MANUFACTURING METHOD:

Not applicable

SHORT RUN MOLDING METHOD:

Tool cost - 40 hrs x $30/hr + material	$1,800
Molding cost - 30 parts/hr x $6.00 + material	
Estimated part cost 25¢ each	

ENGINEERING DETAIL

APPLICATIONS:

Tensile and Impact Test Specimens are used throughout the plastic industry for material quality and process control tests. Tensile and Impact test data are used in the development and improvement of thermoplastic materials.

TOOL: Tool Steel mold base and standard mold components

"A" Plate is suspended from Upper Platen Assembly

Base Plate is toe clamped to table platen

Knock out rods activate ejector plate

Sprue bushing rotates to shoot one cavity at a time

Tensile cavity machined by CNC program or EDM electrode

EXPECTED TOOL LIFE: 100,000 shots or more

PRODUCTION RATE: 30/hour - semi-automatic

EQUIPMENT: Morgan-Press G-55T with Upper Platen Assembly, Heater Plate and Shut-Off Nozzle

Elcut Super 25 EDM machine to generate the tensile specimen cavity

CHAPTER SIX

MATERIAL HANDLING

Each family of thermoplastic materials has its own processing characteristics. To switch from one compound to another may require more than merely readjusting temperatures and pressures. Proper drying (essential for most thermoplastics) and other handling requirements must also be observed. Some polymers not properly processed present hazards to the work environment. Always begin by following the instructions and suggestions of the manufacturer of the material.

When experimenting with a new material or an unfamiliar grade, use an open orifice "B" nozzle first. Establish a good extrusion and note the temperatures. This requires that the material be allowed to drool freely. Once these conditions have been established, a shut-off nozzle can be used to eliminate drooling.

In general, material such as vinyl, urethane, polypropylene, nylon and acetals which drool rapidly, will require low injection pressures (2,000 - 4,000 psi) providing that the gates are adequate in size and the mold temperatures are correct. Materials which drool more slowly such as ABS, phenylene oxide, and polycarbonate will tend to need slightly higher injection pressures (4,000 - 6,000 psi) and larger gates. Heavily filled materials may not drool at all and will require pressure from the ram to extrude from the nozzle. Pressures of 7,000-9,000 psi may be needed to produce good parts. In addition, at each pressure level, the ram speed should be adjusted as needed.

If pressures significantly higher than indicated here are required, it is most probable that the runners and gates are too small and mold venting is inadequate. Excess injection pressure can actually pre-stress molded parts and cause them to be inherently defective. Eliminating mold design deficiencies will ensure better molding results at the correct temperatures and pressures.

Typical problems encountered when molding are as follows:

NYLON

The mold will not fill correctly.

The temperature range at which nylon will flow correctly is rather narrow. A nylon which will drool readily at 580°F may be hard or impossible to move at 570°F. At a sustained 600°F the material will gas, blister, discolor, and flow only as a froth. It is essential with nylon to establish the correct extrusion temperature and to maintain it accurately. Shoot parts at a constant rate and do not attempt to correct short shots by overheating the material. When in contact with the mold, the nozzle temperature will drop rapidly and the nylon in it will chill instantly; so clamp and inject as quickly as possible into a good hot mold.

After shooting, the nozzle will almost invariably be frozen. Wait until it starts to drool again before attempting to shoot another part. If the time required to unfreeze the nozzle is more than two minutes, the nozzle temperature could be raised by 10°F. With the shut-off nozzle, wait until the frozen plug drops free before reshooting.

ABS

Surface color is blemished.

This material has a wide temperature molding range. The problems usually encountered are with surface finish, especially with the dark colors. When the material is plasticized rapidly, the temperature of the extrusion will vary as colder spots, from the center of the cylinder, mix with material nearer the cylinder walls. When injected, these cold spots tend to show up as streaks on the surface.

Always thoroughly dry ABS and pre-heat it for an hour before molding to raise its temperature evenly. In this way even the centers of the granules are heated and the chance of cold spotting will be reduced.

Overheated ABS will also discolor, most noticeably in the lighter colors. When grossly overheated or retained at high heat longer than necessary, the ABS will tend to resolidify and both surface gloss and physical strengths will suffer. ABS compounds tend to gas when heated; molds should be well vented.

ACETALS

Parts are undersize and surface finish is wrinkled.

Acetals have the highest shrinkage rates of all thermoplastic materials. To minimize the effects of shrinkage, parts should be shot as fast as possible, through gates as large as possible into molds heated to 250°F. The injection pressure should be maintained until the gates have chilled, usually three to five seconds after the fill is complete. Acetals are lubricated by the addition of chemicals and only light quantities of mold release are needed on cores or inserts.

Acetal polymers must be handled carefully to prevent accidents. For example, the formaldehyde generated by heating acetals is harmful to eyes and lungs. Good room ventilation is recommended when molding these compounds. This material tends to gas freely; therefore molds should be extensively vented or back pressure will slow the filling. Again thorough drying of this hygroscopic material just prior to its use will substantially minimize gassing and enhance ease of processing.

* * *

The chart on the opposite page summarizes most trouble shooting measures for injection molding.

TROUBLE SHOOTING FOR INJECTION MOLDING

Short Shots or Surface Wrinkles -

Increase ram speed

Increase injection pressure

Increase mold temperature

Increase ram pressure time

Increase runners or gate size

Increase mold venting

Increase time between shots

Sinks –

Increase ram pressure time

Increase ram speed

Enlarge gate

Reduce material temperature

Increase mold venting

Discoloring -

Decrease material temperature

Reduce time between shots

Thoroughly dry material

Thoroughly preheat material

Gassing -

Decrease material temperature

Thoroughly dry material

Preheat material thoroughly

Weld Marks -

Increase mold venting

Increase material temperature

Increase gate size

Move gate or use multiple gate

Increase injection speed and pressure

Add overflow puddle

Warping of Parts -

Reduce mold temperature

Increase ram pressure time

Increase time between shots

Reduce material temperature

Check part design for section variations

Part too Small -

Increase injection time

Increase injection pressure

Reduce material temperature

Enlarge gate

Part too Large -

Reduce injection pressure

Decrease injection time

Dimension Variation Shot to Shot -

Establish and maintain cycle time

Keep mold temperature constant

Maintain constant material temperature

Maintain constant injection pressure

Increase mold venting

Surface Streaking -

Raise mold temperature

Thoroughly preheat material

Thoroughly dry material

Reduce injection rate

CHAPTER SEVEN

INJECTION MOLDING EQUIPMENT

MORGAN-PRESS®
INJECTION MOLDING MACHINES

The Morgan-Press is an all-purpose injection molding machine for prototype and short-run molding of thermoplastics. It is a pneumatic press with air-driven pistons providing the power to clamp molds and inject plastic material into molds. Its temperature range capability permits working with most standard thermoplastic materials as discussed in Appendix III. Unique and patented design features give the Morgan-Press a truly practical utility without comparison.

The Model G-55T is rated at a two-ounce maximum single shot size, the G-100T delivers a four-ounce maximum single shot and the Model G-125T has a five ounce maximum single shot. Manual and semiautomatic capabilities allow semi-skilled personnel to become proficient molders and produce several hundred parts per hour depending on the complexity of the tool. Safety guards, interlocks and point of operation warnings are installed to prevent physical danger to the operator.

Compressed Air and Electrical

The best air pressure range for effective use of the Morgan-Press is between 120-150 psi. If only 100 psi is available from the source (compressor), the machine will still function well; however the maximum available clamp pressure will be limited to 12 tons. Maximum injection pressures will be correspondingly lower depending on the model.

The Morgan-Press operates off a standard 120 volt electrical outlet. Units for 240 volt/single phase electric operation can also be provided.

Pressure Settings

Clamp System

The orange knobs on the lower panel (left side) control the movement of the machine table or the clamp system. Maximum clamping force is generated at 160 psi air input. This exerts a maximum thrust of 40,000 lbs. (20 tons) for Models G-55T, G-100T, and G-125T which are all air driven toggle clamping units. These toggle units are also designed to provide positive return of the clamp table for use with part ejector systems.

Injection System

The black knobs on the lower panel (right side) control the movement of the barrel piston or the injection system. At 160 psi the ram can generate a maximum pressure at the nozzle of 12,000 psi (G-100T), 13,500 psi (G-55T), or 9,000 psi (G-125T). The injection cycle time can be run in semi-automatic operation.

Relationship of Clamp to Injection Pressures

The clamp force holding the mold closed must exceed the total internal pressure to be generated within the mold cavity or the mold will open (flash) during injection.

FOR EXAMPLE: assume an injection pressure of 5,000 psi, a mold with 3 square inches of cavity area at the parting line of the mold and a viscosity factor* of .7: the internal pressure = 5,000 psi x 3 square inches x .7 = 10,500 pounds; thus the selected clamp force must exceed 5¼ tons.

If the internal cavity pressure of a specific mold design should exceed the 20 tons clamp force applied by the Morgan-Press, the mold halves can be bolted together. (See pages 48 & 50).

A good rule is to start with minimum calculated clamp force and low injection pressure and increase the injection pressure and/or ram speed after each cycle until the mold is properly filled. When proper injection settings are attained, the clamp force should be set at the lowest tonnage necessary to keep the mold shut. This minimizes mold and equipment fatigue.

Temperature Settings

Heater Controls

Two electronic temperature controllers are used to maintain the dual zone plasticizing barrel assembly. A melt process range of 0-800°F (32 - 427°C) permits the unit to reach and accurately maintain temperatures for processing of a wide variety of materials.

Temperature Guide

The chart on the front of the machine table is a guide to temperature settings for various materials. For more details, refer to Appendix III and the manufacturers' recommendations.

Manual Operating Cycle

Set-up

A. Select Temperature Control Settings for the material to be used and fill the barrel with material.

B. Select Pressure Settings for Clamp and Injection.

C. Place the mold on the table of the Morgan-Press taking care to locate the mold so that the sprue is beneath the nozzle. Adjust table height according to operating instructions.

D. Wait until the material is at the desired temperature and drooling slowly before attempting to mold.

---

*Viscosity factors are related to the flow characteristics of a specific thermoplastic. These factors are purely arbitrary since the flow characteristics of a thermoplastic may vary with changes in material temperature, mold temperature and mold design.

Molding

E. Lower the table actuating guard until it contacts the table and the actuator pin is fully seated in its hole. Push in the orange knob (clamp control).

F. With chute area guard snapped shut, push in the black knob (injection control): the ram will inject the molten material.

G. Pull out injection control knob, releasing the injection pressure. Pull out the clamp control knob (orange) thus lowering table platen. Raise the guard, remove the mold and then the part.

Semi-Automatic Operating Cycle

When all operating conditions are correct and good parts are being produced manually, the machine may sometimes be converted to semi-automatic operation. Before designing a semi-automatic mold a cost analysis should be made to determine whether the extra tooling cost will be economically beneficial. Part requirement per year is usually the deciding factor, although difficulty in handling the mold may also be an issue.

With a mold design similar to the case examples on pages 86 and 90, cycle time can be reduced considerably. These molds are mounted in the machine; and the machine, rather than the operator, opens and closes them during the clamp/unclamp operation. Knock-out rods installed in the machine activate an ejector plate with ejector pins which are built into the mold. The pins, in turn, push the part (or parts) up out of the mold cavity enabling an operator to quickly and easily remove them.

The Morgan-Press has a pneumatic cycle timer valve which can be set to maintain a constant injection time; thus cycle repeatability and part consistency can be maintained during the production run.

* * *

Shut-down of the Morgan-Press is simpler than the set-up, and the unit requires very little regular maintenance. Full, detailed operating instructions, safety precautions and troubleshooting recommendations to maximize your molding process are provided with purchase of the equipment.

Three Standard Models Available

Morgan Industries has three distinct models to serve your specific requirements. All units can accommodate up to an 8" x 11" mold plan and accept the full range of accessories.

Morgan-Press Model G-55T - designed for efficient short-run applications. It provides a two ounce shot capacity and a positive 20 ton toggle clamp with power return stroke for parts ejection.

Morgan-Press Model G-100T - this is our finest and most versatile machine! This model has a four ounce single shot capacity, as well as positive 20 ton toggle lock clamp and positive part ejection. It accommodates molds from simple cavity plates to standard tool steel bases for the simplest prototype job to higher speed short-run applications.

Morgan-Press Model G-125T – this model has a five ounce shot capacity (but lower maximum injection pressure of 9,000 psi). It was originally developed for larger parts made from easy flowing materials. In use, however, it has proved suitable for use in most other applications as well.

Specifications Common to All Models

0-800°F (0-430°C) temperature control range

Mold plan area 8" x 11"

Utilities Needed: 120 VAC & Compressed air to 160 psi (max)

Digital Temperature Controllers - advanced solid state 3-mode, time proportioning and programmable temperature controls for greater accuracy over a temperature range of 0-800°F - especially useful with high temperature and heat sensitive thermoplastics. Temperature and set point readouts assist in documentation of critical applications.

Injection Speed Control - provides variable ram injection speed which allows plastic processing at lower temperatures and pressures. Also, aids in the processing of some engineering thermoplastics and the filling of large mold cavities.

Optional Equipment

The following items are offered as optional equipment.

Pre-Heat Plate - positions on machine table to heat mold and maintain mold temperature for more consistent parts. Heating molds also makes possible the use of high temperature molding materials.

Anti-Drool Nozzle - prevents excessive drooling between shots. It is particularly useful with materials such as nylons, acetals and polycarbonates which drool at melt temperature. Allows packing of the barrel for maximum shot size. It also keeps material positively shut-off during semi-automatic operation to keep material drool out of mold between shots.

Nozzle Adapter - facilitates testing of prototype molds with standard ball end nozzle or for molds with reverse tapered sprues.

Pneumatic Hook-Up Kit – contains all the components to make installation of a Morgan-Press even easier. It includes a shut-off valve, in-line filter and lubricator, quick disconnects and all fittings and hoses to connect the machine to the compressed air outlet.
